Inngangur

Hólar í Hjaltadal voru höfuðstaður norðurlands um aldir og geyma í jörðu miklar upplýsingar um sögu kirkju og þjóðar. Þar hefur aðeins verið ráðist í takmarkaðar fornleifa- og sagnfræðilegar rannsóknir, þrátt fyrir að til séu ítarlegar fornar ritheimildir um staðinn. Hólar eru því í fornfræðilegu tilliti að miklu leyti óplægður akur, en einstaklega frjósamur; t.d. eru þar leifar einstakrar húsaþyrpingar með rannsóknum sumarsins hefur verið afla ógrynni af nýjum upplýsingum um Hóla í Hjaltadal. Engin fornleifarannsókn hefur farið fram á bæjarhólnum að Hólum í Hjaltadal fram að þessu. En ein helst niðurstaða summarins er fornleifum hefur ekki verið spillt jafnmikið og óttast var. Þó að sléttuð hafi verið yfir bæjarstæði virðast minjar eldri en frá 19. öld ekki hafa orðið fyrir raski. Á helsta minjasvæðinu komu í ljós leifar af mannvirkum sem virðast vera af prentsmiðjuhúsunum á 18.öld en sjálft prenthúsið er ekki en komið fram. Á því svæði sem öskuhaugar Hóla eru komu í ljós óvænt leifar af húsi, eldstæði frá fyrstu tíð.

Gripir úr uppgræftrinum á Hólum

Áður en uppgröftur hófst á Hólum var gert ráð fyrir að þar myndi finnast tölувert magn gripa, enda hefur reynsla sýnt það frá sambærilegum

biskupstólins. Talið var að þetta svæði lægi fyrir utan sjálfa byggðina.

Rannsóknin 2002

Hólarannsóknin er samstarfsverkefni þriggja stofnanna; Hólaskóla, Byggðasafns Skagfirðinga og Þjóðminjasafns Íslands. Rannsóknin eru kostuð af styrk úr Kristnihátiðarsjóði og er gert ráð fyrir að hún muni standa yfir frá 2002-2007. Rannsóknin hefur líka notið fjármagns og tækjabúnaðar frá stofnunum sem standa á bak við hana. Samstarfsstofnanir hafa með ýmsu móti lagt eithvað til rannsóknarinnar og vill rannsóknin þakka þeim og öllum starfmönnum, heimamönnum og þeim sem á einhvern hátt hafa tengst rannsókninni fyrir frábært framlag til Hólarannsóknarinnar.

Uppgröfturinn hófst formlega með því að menntamálaráðherra tók fyrstu skóflustunguna 1. júlí á uppgraftarsvæðinu með műrskeið sem er táknaðt þar sem műrskeið er eitt helsta verkfæri fornleifafræðinga (www.holar.is/holarannsoknin).

Áður en að því kom hafði fjarkönnun (viðnámsmælingum, leiðnimælingum o.p.h.) frá sumrinu áður verið haldið áfram í samvinnu við vísindamenn á vegum Johns Steinbergs

Tómas Ingi Orlích, menntamálaráðherra

frá UCLA háskólanum í Kaliforníu. Einnig var með markvissum hætti farið yfir svæðin með borkjarna og fosfat mælt í jarðvegi; þær rannsóknir eru hluti af doktorsverkefni Douglas Bolenders.

Með hliðsjón afniðurstöðum úr framangreindum athugunum var ákveðið hvar á Hólum skyldi grafið fyrst, hvaða svæði skynsamlegt væri að opna. Ljóst var að mannvistarleifar væru víða, en greinileg mannvirki á svæðum sem gefin voru heitin B og D. Það kom líka heim og saman við túnakort af Hólum, en niðurstöður mælinganna voru bornar saman við þessi túnakort sem til eru af staðnum, hið elsta frá 1887.

Sex uppgraftarsvæði voru opnuð, þrjú fyrir framan kirkjuna, A, B og C, tvö fyrir neðan veg sunnan við kirkjuna, D og E, auk þess sem grafið var nálægt kirkjugarðsveggnum að sunnan á svæði F.

Markmið

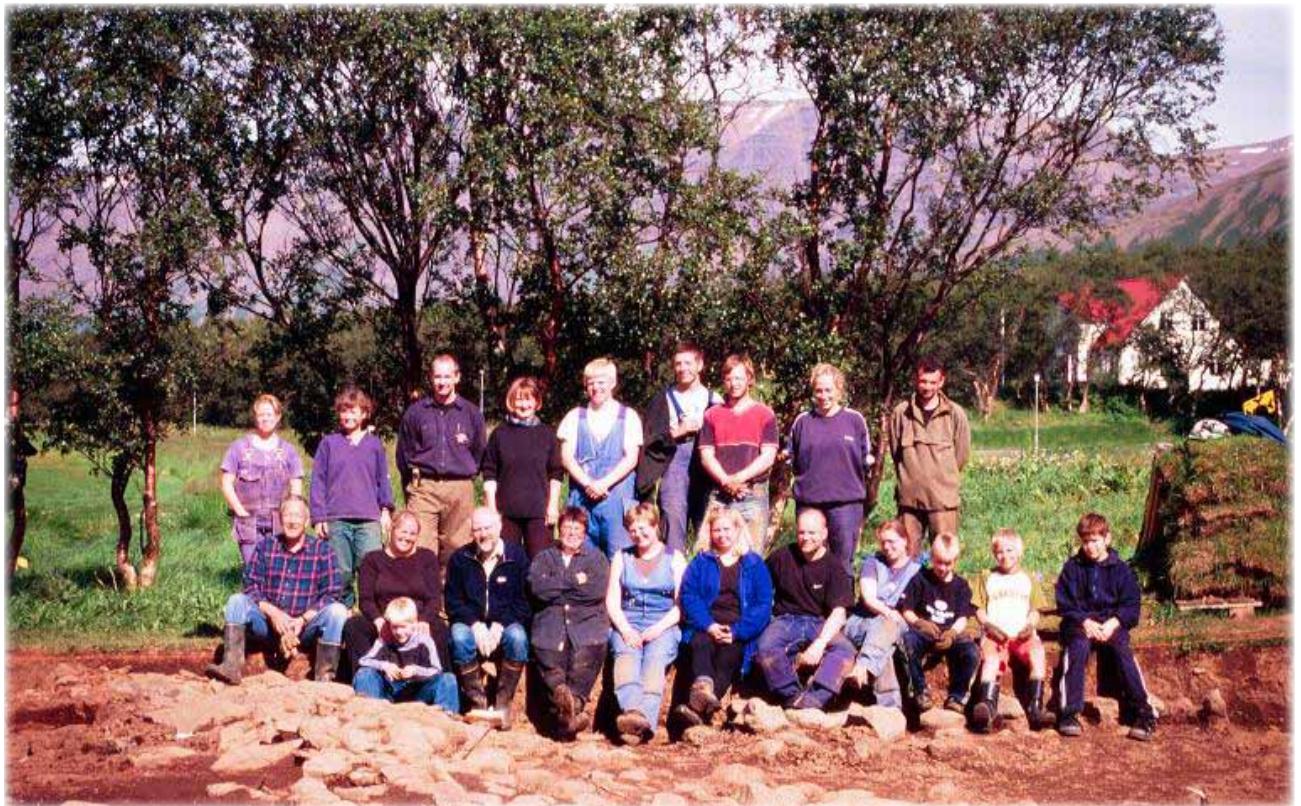

- Ráðast í löngu tímabæra fornleifafræðilega og sagnfræðilega rannsókn á Hólastað.
- Leggja grunn að þverfaglegum rannsóknum á Hólum og þar með efla starfsgrundvöll íslenskrar fornleifafræði til frambúðar með þjálfun stúdenta, fræðimanna, samvinnu innlendra og erlendra vísindamanna, útgáfu og kynningum.
- Styrkja starf ferðamálabrautar og menningartengda ferðaþjónustu á Hólum á fræðilegum grundvelli, til þess að vekja almenning til vitundar um íslenska menningarsögu.
- Kanna efnahag biskupanna/biskupstólsins.
- Kanna skipulag “þorpsins”.
- Rannsaka lífshætti íslenskra yfirstéttu á mismunandi tíum og félagslega samsetningu.
- Kanna húsagerð (hvergi gefist tækifæri til að grafa upp jafnmargar mismunandi húsategundir á einum stað).
- Kanna tengsl við aðra staði tengda Hólum, s.s. Hof, Kolkós, Þingeyri, Reynistað o.fl.

Aðferð

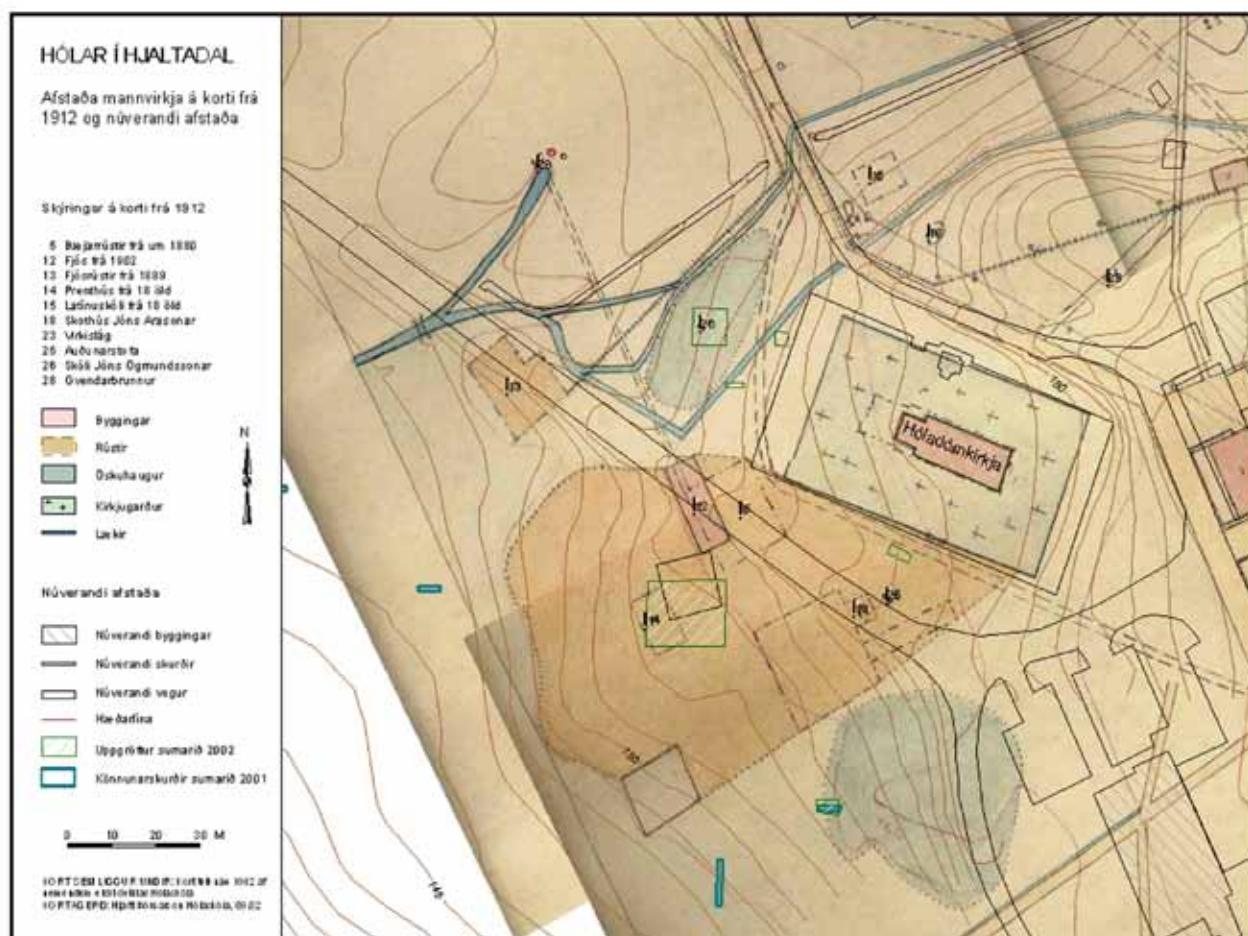

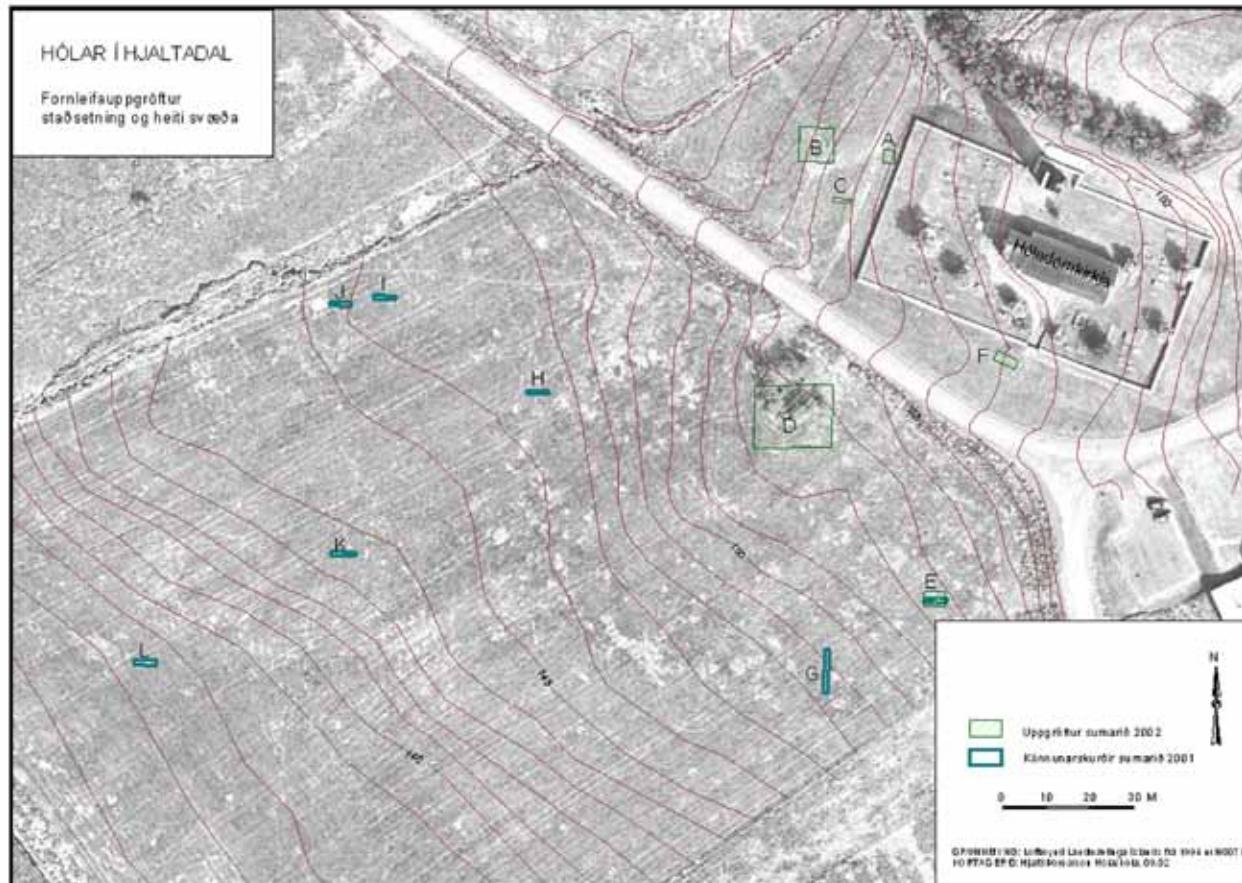

Grafið var eftir jarðlögum, aðferðin nefnist “Harris Matrix”. Með þeirri aðferð er síður hætta á að innbyrðis- og heildarsamhengi svæða glatist og auðveldara er en ella að hafa yfirsýn yfir uppgröftinn. Öll jarðög voru teiknuð og skráð jafnóðum og þau komu fyrir. Við rannsóknina var gerð tilraun til að fullnýta alstöðina, mælitæki sem Þjóðminjasafn Íslands léði rannsókninni, með þeim hætti að mælingarnar voru allar vistaðar í stöðinni og

var þá hægt að setja þær beint inn í rafrænan kortagrunn sem til er af Hólum. Miðað við reynsluna sem þegar hefur fengist mun þetta auðvelda alla teiknivinnu og kortagerð auk þess sem hún verður hárnvæm. Fengnir voru mælingamenn frá Stoð á Sauðárkróki til að setja fasta hnitapunkta í landshnitakerfinu Ísnet. Voru settir út fastapunktar á Reykjum, Hofi, Hólum, Kálfstöðum og Kolkuósi, sem þjóna þeim tilgangi að vera viðmið við aðrar mælingar, t.a.m. við að mæla upp og staðsetja rústir á jörðunum nákvæmlega.

Uppgraftarsvæðið var sett inn í hnitakerfið (Ísnet). Voru jarðlög, jarðfundnir munir, sýni og hleðslur mæld eftir hnitakerfinu, hæðarmæld, teiknuð og ljósmynduð. Gripir, jarðlög, teikningar, ljósmyndir, greiningar o.fl. verða tölvuskráðar í Sarp, gagnagrunn Þjóðminjasafnsins.

Starfsfólk Hólarannsóknarinnar 2002

Svæði A

Ekki komu mannvirki í ljós á þessu svæði með viðnámsmælingum, en með borkjarnanum fundust mannvistarleifar; torf með gulri 1104-gjósku, kol og gjall. Svæðið sem var opnað var 3 m x 3 m að stærð og er fyrir neðan kirkjugarðsvegginn að vestan. Því miður voru öll mannvistar�og hreyfð, sennilega vegna síðustu framkvæmda við kirkjugarðsvegginn. Torf sem fannst er sennilega úr vegg og gæti verið úr eldri kirkjugarðsvegg. Í torfinu var 1104-gjóska og bendir því til að veggjaleifarnar séu gamlar. Ekki fundust margir gripir á þessu svæði, en þó einn hálfunninn snældusnúður úr sandsteini úr Hólabyrðu.

Svæði A

Svæði B

Samkvæmt gömlu túnakortunum var öskuhaugur á svæði B, lítið mannvirki, sem ekki er vitað hvaða hlutverki gegndi, og skóli Jóns Ögmundssonar. Við viðnámsmælingarnar fundust skýr merki eftir húsið sem sýnt er á túnakortinu. Engin önnur mannvirki komu í ljós en glögg merki um að á svæðinu væru mannvistarleifar. Var ákveðið að opnað yrði nógu stórt svæði til að allt húsið kæmi fram í planinu.

Fljótlega var staðfest að húsið var frá 20. öld. Ekkert bendir til að það hafi verið reist fyrr og hlutverk þess er enn á huldu. Þess var þá freistað að grafa þversnið í gegnum það til að kanna hvort eldri mannvirki væru að finna þar undir. Efstu lögum reyndust vera hreyfð, blanda af torfi og ruslalagi, en mikið fannst af gripum, allt frá

miðöldum og fram á 20.öld.

Í sniðinu komu mörg mannvistar�og og mannvirki í ljós, torfveggir, gólfflag og leifar af öskuhaugi. Virðast mannvistarleifar ná aftur til elsta tíma biskupsstólsins. Í neðstu lögum fundust gripir frá miðöldum, bökunarhellur og pottabrot úr klébergi, sem innflutt eru frá Noregi. Greining á plöntuleifum sýnir að varðveislusklilyrði eru góð í gólf laginu sem sást neðst í sniðinu. Niðurstöður úr uppgreftinum á þessu svæði eru mjög spennandi. Þarna er að finna leifar frá elsta tíma biskupsstólsins á Hólum og er mikilvægt að kanna hvers konar hús hafi verið reist þarna til forna og hvenær byrjað var að nota svæðið undir öskuhaug. Þess má geta til samanburðar að uppgröftur á svæði E virðist sýna að hús hafi staðið þar frá 11. eða 12. öld og ofan á rústir þess hlaðist öskuhaugur.

Svæði D

Viðnámsmælingar á þessu svæði sýndu mjög greinilegar útlínur á einu húsi og samkvæmt túnakortum höfðu prentsmiðjuhúsin staðið hér. Á þessu svæði var sérstaklega óttast að minjar hefðu raskast mikið þegar sléttan hafi verið yfir bæjarstæði en fljótegla kom í ljós að minjar frá 18. öld voru óskaddaðar að mestu leyti. Trjálundur og stytta af fyrsta skólastjóra bændaskólans á Hólum hafði verið sett niður rétt um 1960. Höfðu þær framkvæmdir raskað svæðinu og náðu niður í minjar eldri en 1800. Stærsta svæði sem var opnað var um 18 m x 14 m.

Mikill fjöldi gripa, og meiri en við gátum búist við, var í efsta laginu, rétt undir grásrotinni og rótum lögum frá 20.öld. Samkvæmt aldursgreiningu eru þeir frá 16. öld og fram á þá 19. Undir þessu lagi var komið niður á mannvirki frá 17.-18.öld. Sigta varð allan jarðveg.

Við rannsóknina kom ekki aðeins í ljós það mannvirkisemhafðiséstvið viðnámsmælinguna, heldur fundust leifar af þremur húsum og er stærsta húsið með að minnsta kosti þremur herbergjum. Veggir og mannvistalög ganga inn í öll snið svo nauðsynlegt verður að stækka svæðið á næsta ári til að reyna fá heildarmynd af þessum húsum. Sérstaklega spennandi verður

Svæði D

að reyna bera saman úttektir og uppgraffinn manvirki á þessu svæði.

Allar rannsóknir og samanburður hingað til benda til þess að við séum búin að finna þau hús sem tilheyrðu prentsmiðjunni á 18.öld. Tveir ofnar fundust á þessu svæði og kakelbrot/ofnflísar. Í úttektum kemur fram að Sabinsky sem byggði kirkjuna á Hólum um 1750 lagaði og mýraði upp kakelofn.

Séð yfir svæði D

Svæði E

Á svæði E er öskuhaugur samkvæmt túnakortum. Með aðferðum viðnámsmælinga sáust ekki nein hús á þessu svæði en greinileg mannvistar�og. Grafinn var könnunarskurður árið 2001 og var hann stækkaður í sumar. Svæðið er um 2 m á breidd og 5 m á lengd. Í öskuhaugnum eru góð skilyrði til rannsókna á plöntum, skordýrum og beinum. Mikill fjöldi gripa fannst líka. Efsti hluti öskuhaugsins er rótaður en þaðan og niður má rekja löginn frá einu til annars aftur til 10. aldar. Nákvæm aldursgreining hefur ekki enn farið fram en fyrir liggar skýrsla Magnúsar Á. Sigurgeirssonar, jarðfræðings, á gjóskulögum úr sniðinu. Undir lok rannsóknarinnar í sumar var óvænt komið niður á eldstæði, gólf og torfveggi í neðstu lögunum sem benda ótvírett til forns bústaðar. Form, afstaða jarðlaga og ekki síst gjóskugreining sýnir að leifarnar eru frá 11. – 12. öld.

Svæði E er því einstaklega spennandi fyrir þær sakir að komið hafa í ljós leifar mannvirkis frá fyrstu tíð biskupsstólsins á Hólum þar sem slíkra fornleifa var ekki að vænta fyrirfram. Þar sem að ekki virðast nein yngri mannvirki hafa verið reist ofan á þessu húsi standa vonir til að leifarnar séu bæði heillegar og upprunalegar.

Eldstæði frá 11. - 12. öld

Svæði F

Í því skyni að rannsaka hvar göng úr kirkjunni til byggðar hafa legið var grafinn skurður á svæði F samhliða kirkjugarðsvegnum, um 1 m á breidd og 3 m á lengd. Svo virðist sem göngin séu fundin en ekki gafst tóm til að grafa almennilega niður í þau. Svæðið er töluvert raskað austanmegin, þar sem grafinn hefur verið framræsluskurður frá kirkjunni eða kirkjugarðsvegnum. Mjög mikilvægt var að finna og sannreyna að þarna hefðu verið göng frá kirkjunni. Staðsetning þeirra gerir kleift að staðsetja fleiri hús út frá heimildum, þ.e. úttektunum á Hólastað. Verður því haldið áfram að rannsaka þetta svæði á næsta sumri.

Svæði F

Helstu niðurstöður

Rannsóknir sumarsins leiddu í ljós ýmsar nýjar upplýsingar um minjar á Hólum í Hjaltadal. Þessar eru helstar:

- Fornleifum hefur ekki verið spillt jafnmikið og óttast var. Þó að sléttáð hafi verið yfir bæjarstæði virðast minjar eldri en frá 19. öld ekki hafa orðið fyrir raski. Enn hefur ekki verið metið hve mikið hefur spillst vegna vegalagningarár, en vegurinn fram Hjaltadal virðist hafa verið lagður á þúða sem kallað er. Varðveislusklírði eru almennt góð og gefa mikla möguleika á rannsóknum af öllu því tagi sem til stendur með Hólarannsókninni.
- Á Hólum er eitt stærsta ‘bæjarstæði’ á Íslandi og í fornleifafræðilegu tilliti eru þar afar forvitnilegar leifar í jörðu.
- Öskuhaugarnir á Hólum eru að minnsta kosti tveir (svæði B og E). Miklir möguleikar eru fólgir í rannsóknum á þeim. Þar sem stór hópur fólks hefur búið í magrar aldir myndast stórir sorphaugar. Vegna góðra varðveislusklírða ætti að vera auðvelt að nýta upplýsingar úr sorphaugunum.
- Greining dýrabeina úr rannsókninni og þá sérstaklega úr öskuhaugnum eru mikilvægur þáttur í rannsókninni. Beinin gefa upplýsingar um fæðu fólks, um hvers konar skepnur voru haldnar á staðnum, hvaða dýrategundir menn veiddu sér til matar og um hlutfallið þar á milli. Greining dýrabeina getur því gefið mikilvægar upplýsingar lífsviðurværi og efnahag á mismunandi tínum.

- Verður sérstök áhersla lögð á að grafa á svæði E en þar fannst gólf og torfveggur í neðstu lögunum sem benda ótvírætt til forns bústaðar. Form, afstaða jarðlaga og ekki síst gjóskugreining sýnir að leifarnar eru frá 11. – 12. öld.
- Svæði E er því einstaklega spennandi fyrir þær sakir að komið hafa í ljós leifar mannvirkis frá fyrstu tíð biskupsstólsins á Hólum þar sem slíkra fornleifa var ekki að vænta fyrirfram. Með því að ekki virðast nein yngri mannvirki hafa verið reist ofan á þessu húsi standa vonir til að leifarnar séu bæði heillegar og upprunalegar.
- Svæði D verður stækkað til að fá sem gleggsta mynd af þeim húsum sem stóðu þar á 18. öld. Verður sérstaklega spennandi að bera saman úttektir og uppgrafir mannvirkis á svæðinu.
- Mjög brýnt er að bjarga þeim mannvistarleifum sem eru hverfa á Kolkuósi. Það er mjög mikilvægt að reyna skilja þýðingu hafnarinnar fyrir Hóla og byggðina í kring.
- Samband Hofs og Hóla er mikilvægt, hvaða áhrif höfðu Hofsverjar á að biskupsetrið skildi verða á Hólum. Hvaða þýðingu hafði Hof í Hjaltadal? Á jörðinni eru stór og mikil mannvirki sem þyrfti að kanna nánar.

Gripir frá Hólum

Ragnheiður Traustadóttir

Áður en uppgröftur hófst á Hólum var gert ráð fyrir að þar myndi finnast tölувert magn gripa, enda hefur reynsla sýnt það frá sambærilegum rannsóknum. En fjöldi gripa var miklu meiri en Áður en uppgröftur hófst á Hólum var gert ráð fyrir að þar myndi finnast tölувert magn gripa, enda hefur reynsla sýnt það frásambærilegum rannsóknum. En fjöldi gripa var miklu meiri en við gátum búist við, sérstaklega á svæði D þar sem komið var niður á mannvirki frá 17.-18. öld. Gripirnir fundust allir í lagi fyrir ofan mannvirkin, rétt undir grásrótinni og í rótuðum lögum frá 20. öld en eru tímasettir til 16. aldar og fram á þá 19.

Unnið var að skráningu og pökkun gripa á vettvangi enda aðstaða fyrir hendi. Ýmsir starfsmenn rannsóknarinnar í sumar komu að skráningu gripa. Raina Stabelsky, fornleifafræðingur og listamaður vann í 3 vikur við að teikna gripi sem fundust við rannsóknina í sumar. (Sjá teikningar)

Munarannsóknir eru eðlilega mikilvægur hluti fornleifarannsóknar á Hólum. Auk vísbendinga um aldur munu fást margvíslegar aðrar upplýsingar við rannsóknir á munum, s.s. um efnisnotkun, verkkunnáttu, verslun, efnahag, tengsl innanlands og við útlönd o.s.frv. Verður sérstök áhersla lögð á að greina gripi úr rannsókninni í vetur. Enn liggar heildarfjöldi

gripa ekki fyrir en áætlað að þeir séu nú um 4000 talsins.

Úrvinnsla og greining á gripum mun fara fram í vetur eftir að þeir hafa verið skráðir. Ýmsir starfsmenn og þátttakendur í rannsókninni munu taka að sér að greina einstaka gripi. Nú stendur til að tveir MA nemar og einn í grunnámi í fornleifafræði skrif um gripi frá rannsókn sumarsins.

Í grófum dráttum fundust eftirtaldir flokkar af gripum:

Gler

Glerbrot af ýmsum gerðum en mikið magn var af gleri úr rúðum, flöskum og lyfjaglösum. Nokkur glerbrot voru skreytt en ekki er vitað hvort brotin eru úr skrautgluggum eða ílátum. Glerperlur fundust einnig.

Glerperla

Leirkar

Leirkarjabrot voru líka stór hluti af gripum sem fundust í sumar, af því sem búið er að gróffflokkar voru leirkarin á tímabilinu frá miðri 16.öld fram á 20. öldina og af öllum gerðum; hvítleir, rauðleir, postulín, steinleir og fajans. Merkilegustu brotin við fyrstu sýn eru Kakelbrot/ofnflísar, trúlega frá miðri 18. öld. Leirkarabrotin verða greind nánar í vetrur. Mun verkefnastjóri greina brotin og leiðbeina Ingu Sóleyju Kristjönudóttur við greiningu á steinleirsbrotum sem fundust.

*Rauðleir**Kakelbrot**Krítarpípur*

Búið er að skrá allar krítapíurnar en heildarfjöldi þeirra er um 560 brot. Brotin eru leggir og hausar. Hægt er að upprunagreina og aldursgreina hluta af þessum brotum með greiningu á mynstri, skrauti og stimplum. Krítarpípur eru fyrst framleiddar í Gouda í Hollandi seint á 16.öld. Eitt brot fannst með nafninu Gouda.

*Krítarpípuleggur**Málmur*

Fjöldi gripa úr málmi, bronsi eða járni, var gífurlegur og eru það járnna glarnir sem eru stærsti hlutinn í þeim flokki en ýmis verkfæri fundust líka og eftirfarandi gripir eru úr málmi: hnifar, tölur, hnappar, vasahnífur, blýlengjur, járnstykki, ýmsir skrautgripir, lyklar o.fl.

*Skrautmunir úr bronsi*

*Hnappar**Steinn*

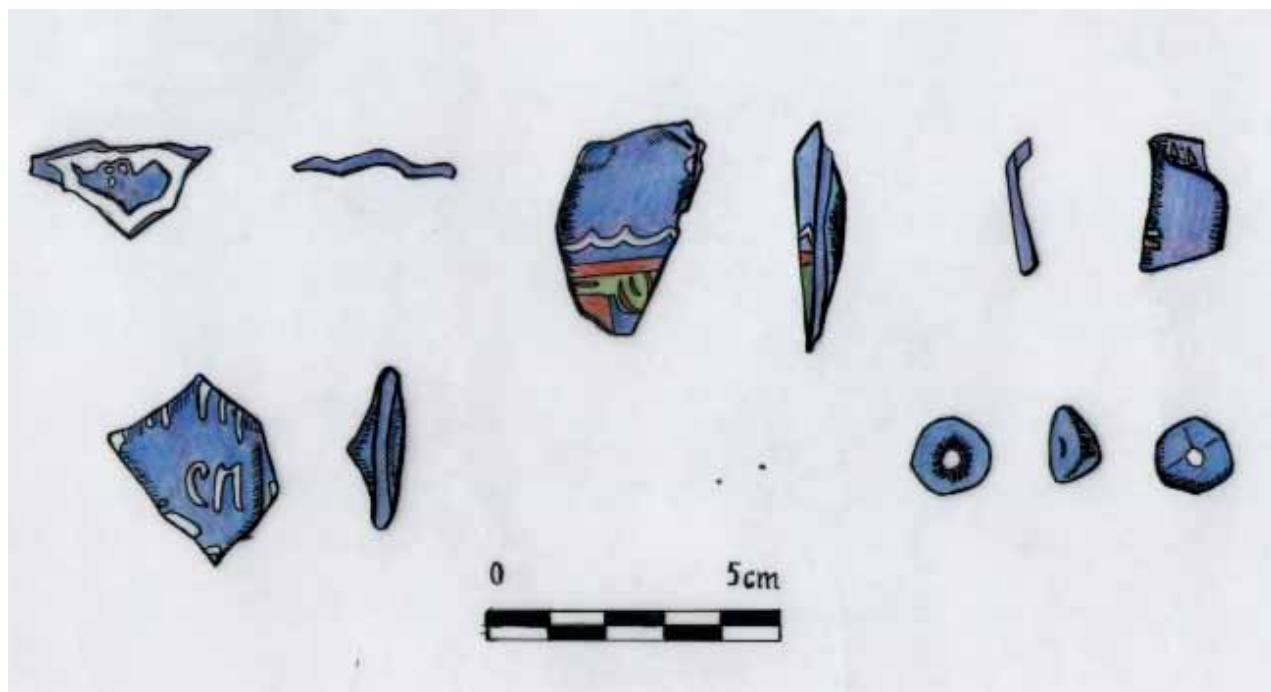

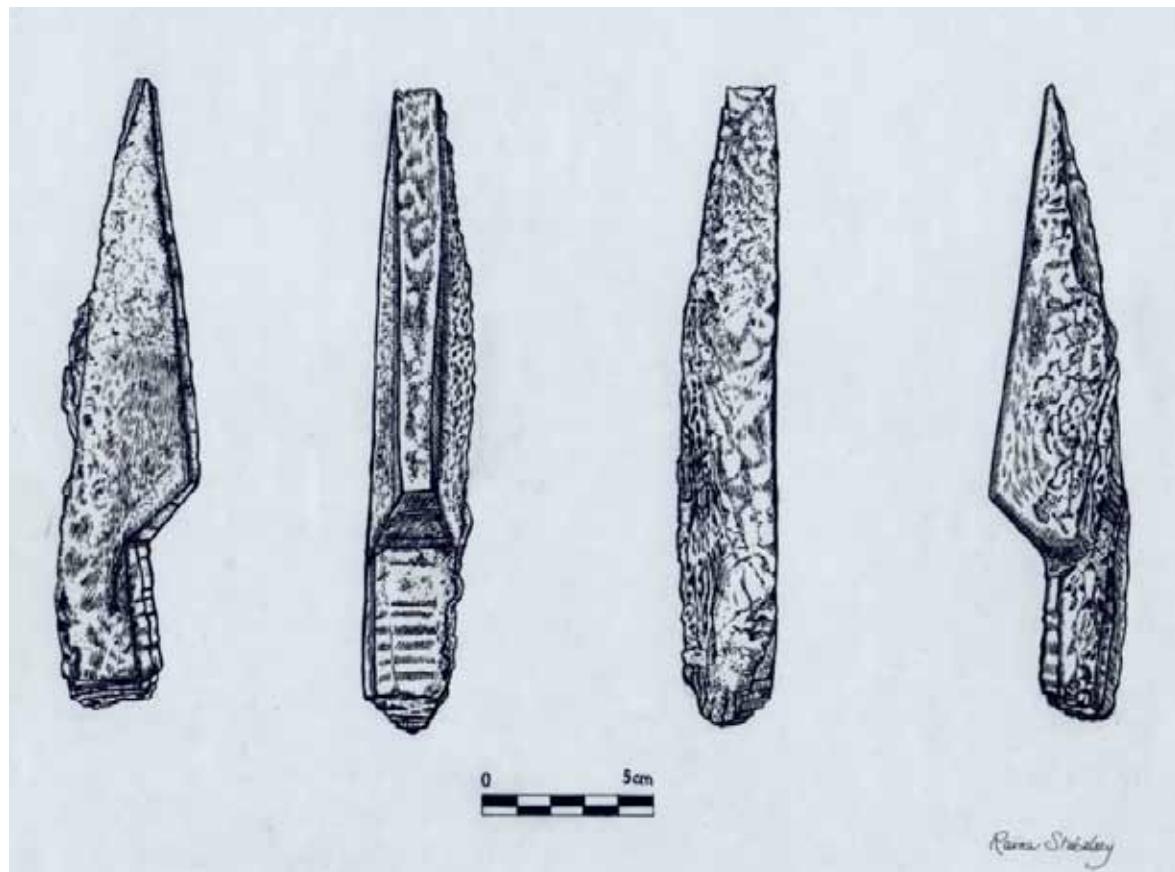

Nokkrir einstaklega fallegir gripir úr steini fundust; kola, perla, bökunarhella og pottabrot úr klébergi. Þessir gripir eru sennilega þeir elstu frá miðoldum. Einnig fannst fjöldinn allur af brýnum, mótt úr rauðum sandsteini til að steypa lýsislampa, o.fl.

*Brýni**Pottabrot úr klébergi**Kola**Bein*

Gripir úr beini voru nokkrir, en merkilegasti gripurinn úr beini er Kotra og gripur sem sennilega er útskorinn hnappur.

Ýmsir aðrir gripir fundust við rannsóknina en skráningu er ekki enn lokið og vinnur Katrín Gunnarsdóttir, fornleifafræðingur á Byggðasafni Skagfirðinga við skráningu og pökkun á Hólum frameftir haustinu.

*Kotra úr beini*

Teikningar eftir Rainu Stabelski

Kynning og leiðsögn á Hólarannsókninni

Hólarannsóknin hefur fengið tölverða umfjöllum í fjölmíðun og með þeim hætti verið kynnt fyrir almenning.

Meðan á rannsókninni stóð í sumar var verið með leiðsögn um uppgraftarsvæði, voru auglýstir fastir tímar á fimmtudögum og laugardögum en tekið var á móti öllum gestum sem komu þegar unnið var við uppröftinn. Páll V. Kolka Jónsson sá að mestu leyti um leiðsögnina. Það var sérstaklega ánægjulegt þegar við komust að því að hópurinn talaði samtals 11 tungumál (ensku, öll Norðurlandamál, rússnesku, úkraínsku, grísku, spænsku, hollensku, þýsku og frönsku). Var því hægt að taka vel á móti erlendum gestum.

Verkefnastjóri Hólarannsóknarinnar kom með þá hugmynd að árlega yrði haldinn sérstakur Fornleifadagur til kynna þær rannsóknir sem Kristnihátíðarsjóður styrkti. Þjóðminjasafnið sá um að stilla saman strengi allra þátttakenda og var sunnudagurinn 28. júlí valinn fyrir viðburðinn. Dagurinn tókst vel og á Hólum tóku allir starfsmenn rannsóknarinnar þátt og fengu börn að sigta með fornleifafræðingum. Það var sérstaklega ánægjulegt hversu margir heimamenn sóttu staðinn heim.

Hólarannsóknin hefur sett upp heimasíðu www.holar.is/holarannsoknin þar sem fjallað er um rannsóknina og reynt að birta fréttir af henni. Sú ákvörðun hefur verið tekin að birta ýmis rannsóknargögn á heimasíðunni svo að þau verði aðgengileg öðrum fræðimönnum. T.a.m.

Fornleifadagurinn

hafa úttektir verið birtar á síðunni. Heimasíðan mun verða á þremur tungumálum; íslensku, ensku og Norðurlandamálum, en það eru þau mál sem rannsóknin notar í sínum samskiptum.

Í undirbúningi er sjónvarpsþáttur um Hólarannsóknina og var safnað efni í sumar á meðan uppgreftri stóð. Þór Jónsson, aðstoðafréttastjóri á Stöð 2, og Viggó Sigurðsson, tökumaður, sjá um verkefnið. Ekki hefur enn fengist fjármagn í verkið og hefur það fram að þessu verið kostað af þeim Þór og Viggó.

Starfsemi sumarið 2002

Rannsóknarstaður: Hólar í Hjaltadal

Rannsóknarnúmer: 37

Uppgraftartímabil: 1. júlí – 17. ágúst

Uppgraftarsvæði voru 6 svæði A, B, C, D og E

Stjórnandi:

Ragnheiður Traustadóttir, fornleifafræðingur

Uppgraftarstjórar:

- Helena Fennö, fornleifafræðingur við Borgaminjasafn Stokkhólms
- John Wandesjö, fornleifafræðingur við Borgarminjasafn Stokkhólms
- Guðný Zoëga, fornleifa og mannabeinafræðingur, minjavörður austurlands
- Angelos Parigoris, MA í fornleifafræði

Aðrir tarfsmenn við uppgröft:

- Anna Rut Guðmundsdóttir, BA í mannfræði
- Anna Lísa Guðmundsdóttir, jarðfræðingur og deildastjóri fornleifadeildar Árbæjarsafns
- Katrín Guðmundsdóttir, fornleifafræðingur við Byggðasafni Skagfirðinga
- Valerie Sonstenes, fornleifafræðingur
- Dr. Fedir Androshchuk, fornleifafræðingur við Stokkhólmsháskóla
- Allan Hansen, nemandi í fornleifafræði
- Inga Sóley Kristjönudóttir, nemandi í fornleifafræði
- Guðmundur Óskarsson, háskólanemi
- Páll Kolka Jónsson, menntaskólanemi

- Ingibjörg Kolka Jónsson, háskólanemi
- Jón Bjarnason, alþingismaður
- Þorsteinn Gunnarsson, arkitekt
- Arna Björg Bjarnadóttir, BA í mannfræði
- Michael Neiß, meistaránemi í fornleifafræði við Stokkhólms Háskóla

Starfsmenn við sýnagreiningar, forvörfslu og fjarkönnun:

- Dr. Magnús Hellqvist, jarð- og skordýrafræðingur við Háskólan í Falun
- Dr. Steve L. Martin, fornleifa- og plöntufræðingur
- Ylva Bäckström, dýrabeinafræðingur við Societas Archaologica Upsaliensis
- Jannie Amsgaard Ebsen, forvörður hjá Þjóðminjasafni Íslands
- Magnús Á. Sigurgeirsson, jarðfræðingur og gjóskulagasérfræðingur
- Tim Horsley, doktorsnemi við Háskólan í Bradford

Starfsmenn við kortagerð, handritalestur og griplateikningar:

- Hjalti Þórðarson, landfræðingur við Hólaskóla
- Rúna Knútsdóttir Tetzschner, háskólanemi og sérfræðingur á Þjóðminjasafni Íslands.
- Raina Stabelski, fornleifafræðingur og griplateiknari

Bókhaldsumsjón:

- Sigurbjörg Ólafsdóttir, Háskólanum á Hólum

Gröfuvinna:

- Hörður Jónsson, ábúandi á Hofi

SSAS

Fornleifarannsóknir í Skagafirði, sem ganga undir vinnuheitinu SASS- Skagafjordur Archaeological Settlement Survey eru unnar af rannsóknarhópi mann- og fornleifafræðinga og jarðvísindamann frá UCLA og North Western hófu samstarf við Hólarannsóknina á undirbúningsárinu 2001 með því að kanna öll tún og bæjarstæði á Hólum með jarðsjám, jarðbor og könnunarskurðum. En markmið hópsins er að kanna horfin jarðlæg hús og afla þekkingar um fornleifar í Skagafirði. Rannsóknin er undir stjórn dr. John Steinbergs, í fornleifafræði við Háskólan í Los Angelos UCLA og við fjarkannanir á Hólum unnu dr. Brian Damiata, jarðeðlisfræðingur, Douglas Bolender, doktorsnemi.

Samstarfsverkefni, stýrihópur og bakhjarlar rannsóknarinnar:

Ragnheiður Traustadóttir, stjórnandi Hólarannsóknarinnar, Skúli Skúlason, skólameistari Hóla, Sigríður Sigurðardóttir, forstöðumaður Byggðasafns Skagfirðinga, og Margrét Hallgrímsdóttir, þjóðminjavörður.

Samstarfsaðilar:

- Vígslubiskupinn á Hólum í Hjaltadal
- Héraðsskjalasafn Skagfirðinga
- Byggðasaga Skagafjarðar, Hjalti Pálsson sagfræðingur
- Högskolan i Dalarna, Magnus Hellqvist,

Gjóskulagagreining

Magnús Á. Sigurgeirsson

Þann 14. ágúst voru gjóskulög skoðuð á uppgraftarsvæðinu á Hólum í Hjaltadal. Leitað var eftir gjóskulögum í torfi á bæjarhólnum, í veggjum meintrar prentstofu. Mest áhersla var þó lögð á að skoða og mæla upp snið í austurjaðri bæjarhóls þar sem skurður hafði verið grafinn í gegnum mannvistarlag, aðallega sorp- og torflög (mynd 1).

Gjóskulög í Skagafirði

Gjóskulög hafa verið könnuð í Skagafirði á síðustu árum í tengslum við fornleifarannsóknir þar (Magnús Á. Sigurgeirsson 1998, 2000, 2001). Varðandi umfjöllun um einstök gjóskulög víast til þeirra athugana. Auk þess skal bent á ýtarleg athugun á gjóskulögum í Austurdal og Vesturdal í Skagafirði (Gunnar Ólafsson 1985, Guðrún Sveinbjarnardóttir 1992). Þau gjóskulög á Skagafjarðarsvæðinu sem að mestu gagni koma við aldursákvörðun fornleifa eru eftirfarandi:

1. Landnámssyrrpa (LNS). Í henni eru 3-4 basísk gjóskulög sem öll eru þunn í Skagafirði, en hins vegar sitja þau jafnan í mjög dökku jarðvegslagi sem sker sig vel frá jarðvegi ofan þess og neðan.
2. V~1000 (s.g.~1000). Þetta gjóskulag er allskýrt í vestanverðum Skagafirði.

3. H-1104 (H1). Finnst víðast hvar í Skagafirði en er þó misvel varðveitt.
4. H-1300. Eitt auðgreindasta gjóskulagið af þeim sem hér eru upp talin.
5. V-1477 (a-lag). Hefur aðeins fundist á einum stað, skammt sunnan Hofsóss.
6. H-1766. Finnst víðast hvar á Skagafjarðarsvæðinu.

Sýnataka - smásjárskoðun

Þrjú gjóskusýni voru tekin til frekari skoðunar úr torfi í sniðinu sem mælt var (mynd 1). Í smásjá má draga fram ýmis einkenni gjóskunnar sem ekki eru sjáanleg berum augum og verður greining einstakra gjóskulaga því mun áreiðanlegri sé slíkri skoðun beitt.

Sýni nr. 1: Einkennist af margbreytilegri kornagerð. Litr gjóskuglersins er gulbrúnn-dökkbrúnn-grár-svartur. Einnig er nokkuð um rautt gjall. Gráleit vikurkorn eru mest áberandi. Dökkar smáar innlyksur eru greinilegar í ljósari kornunum. Gjóskan er mjög illa aðgreind, þ.e. kornastærð er mjög breytileg. Gjóskan ber skýr einkenni Heklugjóska. Telja má víst að um sé að ræða gjóskulagið H-1300. Þess skal getið að greina má á milli gjóskulaganna H-1766 og H-1300 í smásjá.

Sýni nr. 2: Súr gjóska, fremur gróf. Hnöttótt hvít vikurkorn eru einkennandi. Einnig er talsvert af tærum kristöllum. Dökkar innlyksur eru í gjóskunni. Rauð gjallkorn eru áberandi. Telja má næsta víst að um Heklugjóska sé að ræða, sennilega Heklu-1 frá árinu 1104.

Sýni nr. 3: Basísk gjóska úr mógrænu gleri. Einkennandi eru mjög blöðrótt korn með fíngerðan textúr, þunna og skarpa blöðruveggi. Einnig er til staðar óblöðrótt glerkurl. Dálítið er um dökk ógegnsæ glerkorn. Gjóskan er mjög illa aðgreind. Af samanburði við önnur gjóskusýni gæti verið um að ræða gjóskulagið V~1000.

Niðurstaða og ályktanir

Mannvistarlagum í sniðinu er skipt í fjórar einingar (I-IV) með tilliti til breytinga í lit og strúktúr (mynd 1). Skil eru í sorplögunum á um 70 cm dýpi, neðar verða þau ljósari og þéttari. Gjóskusýni nr. 1 var tekið á um 65 cm dýpi, rétt ofan skilanna (í einingu I). Telja má víst að þetta sýni sé úr gjóskulaginu H-1300.

Gjóskusýni nr. 2 og 3 eru tekin úr gjóskuflekkjum úr torfi á um 95-103 cm dýpi, í einingu II, rétt ofan við eldstæði sem gengur inn í sniðið. Nánari skoðun á sýnum bendir til að um geti verið að ræða gjóskulögini H-1104 og V~1000. Samkvæmt því eru sorplögini næst ofan við eldstæðið frá því eftir 1104. Ekki tókst að finna gjóskulagið H-1300 í einingu II. Æskilegt væri að gera frekari leit að laginu þar.

Eining III, á 105-113 cm dýpi, er þétt sorplag með beinum, koli og móósku. Ekkert torf var

sjáanlegt. Eldstæðið er efst í þessu lagi.

Í einingu IV, á 113-154 cm dýpi, er mest einkennandi torf með LNS og forsögulega gjóskulaginu Heklu-3. Landnámssyrpan kemur í ljós skammt neðan hennar á um 158 cm dýpi.

Þær vísbindingar sem gjóskulögini gefa um aldur eininganna fjögurra eru eftirfarandi:

Eining I: Mynduð á 14. öld og síðar (yngsti hluti þess er frá 20. öld).

Eining II: Mynduð á 12. öld og/eða síðar

Eining III-IV: Mynduð á 10. öld og/eða síðar

Primarily Conservation

Jannie Amsgaard Ebsen

The excavation at Hólar, Hjaltadalur of 2002 recovered a large amount of finds. The finds cover a big variety of inorganics as well as a small quantity of organics. The inorganics being various fragments and objects made of ceramics, glass and metal. The material groups of the organics consist of textile, leather, bone and wood. The finds were generally cleaned with water, dried and packed in polyethylene bags or boxes with acid free tissue paper and registered "on site" in Hólar and labeled with Hólar 2002-37- and the find number. The conservation, of so fare 120 selected metal find numbers and 20 find numbers covering organics, are now taking place at the conservation covering repacking with inert supporting materials and creating desiccating environments for certain materials.

Inorganics

Copper alloys etc. (Bronze, silver and lead).

Some of the copper alloys seem to suffer from active corrosion ("Bronze-disease") with the formation of light greenish copper chloride products. Otherwise most of the copper alloys are quite mineralized and fragile and in need of stabilizing treatment. The objects are being cleaned mechanically under microscope to remove unwanted corrosion products and to find the "original surface" of the objects. This is followed by vacuum impregnation with the

inhibitor benzotriazole and the consolidant/laquer Paraloid B 44.

Iron

The iron objects will be cleaned for unwanted corrosion with air-abrasive equipment, unwanted salts will be removed in a desalination process and finally the objects will be vacuum consolidated with microcrystalline wax or Paraloid B 72. Before conservation they are being stored in a desiccating environment with silica gel.

Organics

Textile, wood, leather and bone

The damp textile, wood and leather will be cleaned with water and consolidated in polyethyenglycol (PEG) with different concentrations and molecule sizes. Then the objects will be freeze dried to prevent collapse and deformation. The fragile bone objects will be consolidated with Paraloid B72 and a good supporting packing will be made.

Remote Sensing and augering of the north field at Hólar

John Steinberg

The Hólar 3 field is situated just east of the Hólar church. It was surveyed on the morning of Friday June 28 by Brian Damiata using the EM-31, assisted by Steve Martin and Linda Rehberger. The field was surveyed North-South, with 1 m between stations and 0.5 m between readings. The survey was accomplished during a morning with dry and sunny weather.

The 2607 readings averaged 12.1 ms/m, with a range of 3.9 to 22.8 and a standard deviation of 2.0. Over 50% of the readings were between 10.5 and 13.5. The maximum change between adjacent readings or, maximum apparent

conductivity contrast, averaged 0.05, with a standard deviation of 1.29 and had a range of -6.3 to +6.3. These numbers indicate a relatively smooth and consistent survey.

The readings (Figure 2) revealed 3 major anomalies. A linear low conductivity feature running northwest from 400,70 to 410, 715, a small sharp low conductivity anomaly at 404, 724 and a high conductivity area at 415,745. These features are reinforced by the conductivity contrast map (Figure 3).

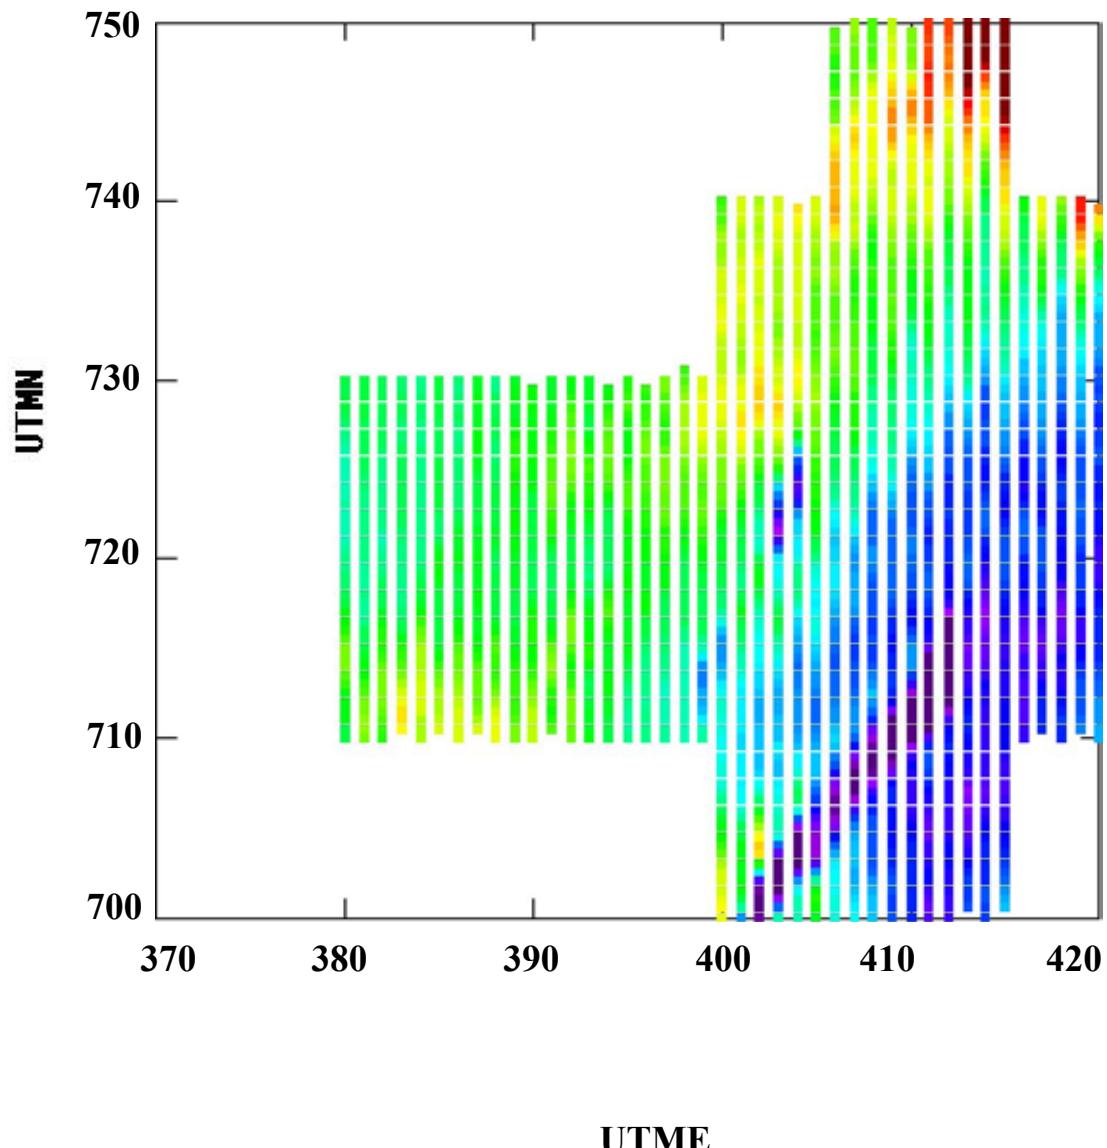

Figure 2. Conductivity map of Hólar 3. The range is from low conductivity (violet) 7.7 ms/m to high (red) 17 ms/m.

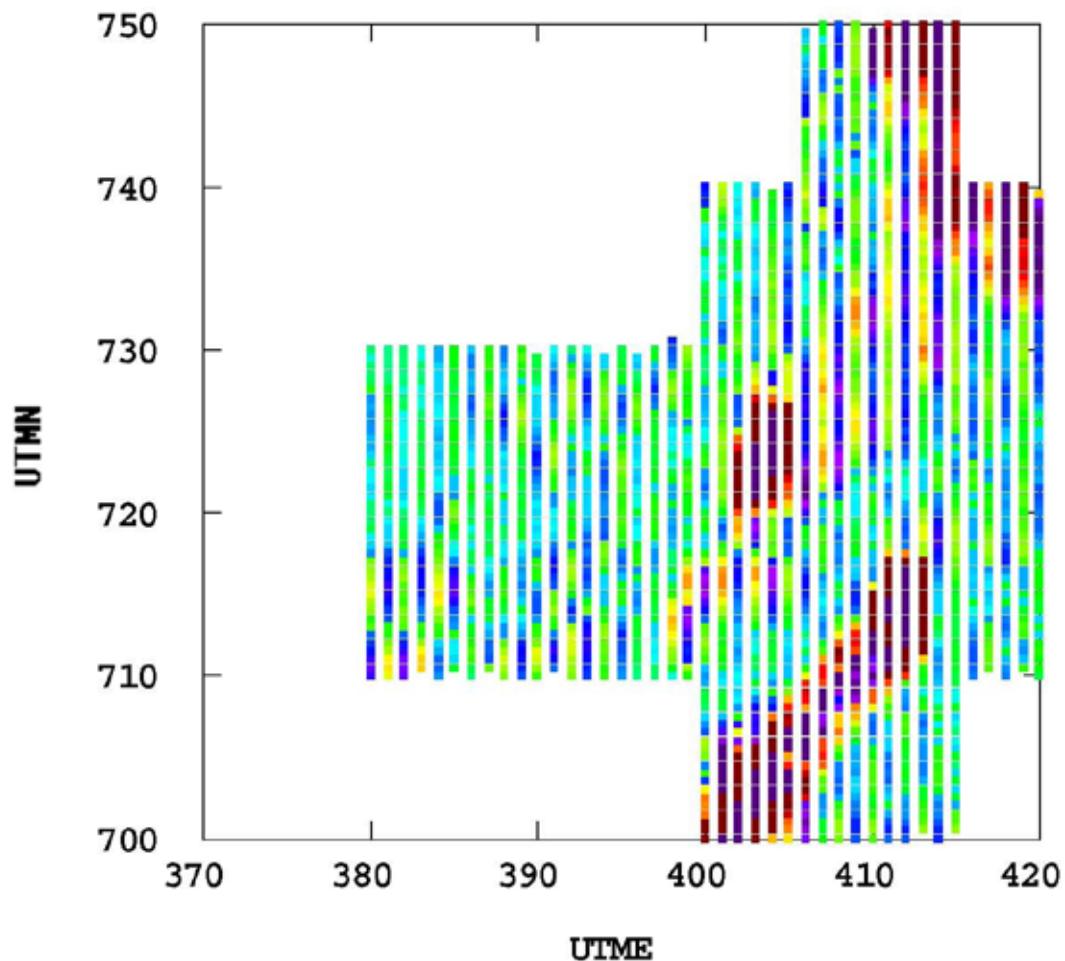

Figure 3. Conductivity contrast map of Hólar 9.

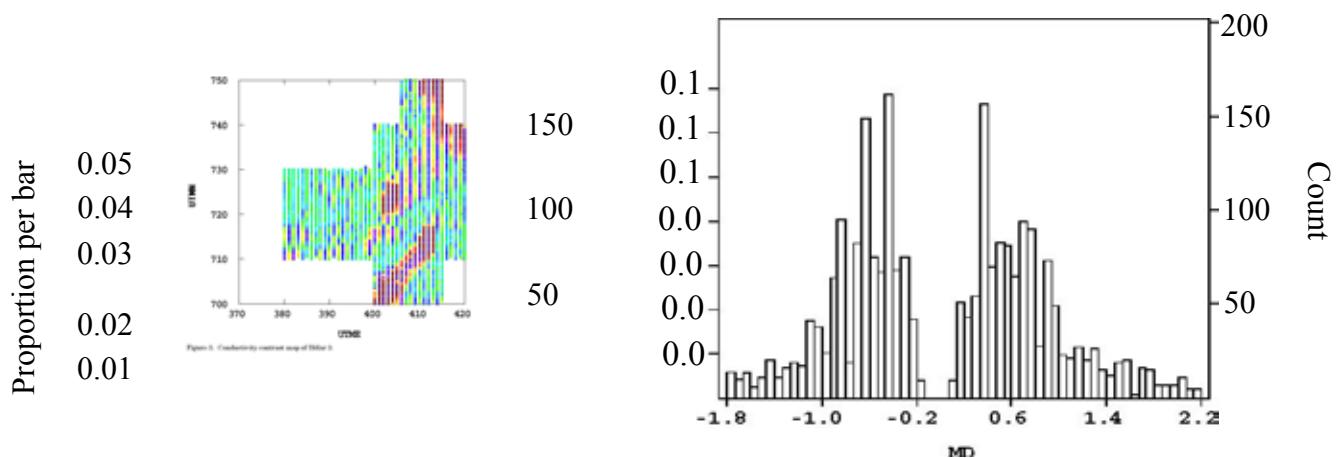

Figure 4. Histograms of conductivity (left) and conductivity contrast (right) from EM-31 readings at Hólar. The scales of the histograms correspond to the violet – red scales in Figure 2 and Figure 3 respectively.

Auger Holes

Four auger holes were excavated at Hólar 3. Primarily, there were put into apparent anomalies, features, though not the northern, high conductivity anomaly. Holes 404,724 and 410,710 were put in to investigate low conductivity anomalies, the former, for the small one, and the latter to investigate the liner anomaly. All measurements are in cemeteries below ground surface.

404,724

Placed to investigate low (6 ms/m surrounded by 12 ms/m readings). It is likely that metal, placed into an old structure produced this anomaly. In all likelihood, the metal hid the low conductivity signatures of the turf wall.

0-16 Top soil with little cultural material

16-29 black greasy layer with metal of various sizes.

30-34 black organic clay

34-86 Turf wall.

86-107 sterile loose clay with organic matter

107-123 ice age moraine

123 bottom.

710,420

Placed because core could not go deeper than 12 cm and because there is a structure on a map from 1917. No significant anomaly was

observed on the remote sensing.

0-10 top soil

10-15 turfs mixed with charcoal.

15-40 Undifferentiated soil mixed with burnt rock and charcoal

40-50 Charcoal deposit

50-55 Organic brown soil

55 bottom

420,719

Placed because 420,720 had large stones and could not be continued below 15 cm. Placed in the eastern most section of a large area of low conductivity. No specific change in conductivity was observed associated with the location. On the Northwest side, form 20 to 38 cm down, a collection of rocks in a possible artificial arrangement. The fill around these rocks contains charcoal, bone and burnt red stone.

0-20 top soil

20-24 Charcoal and soil

24-27 yellow tephra (probably prehistoric Hekla)

27-38 Orange soil

38 Bottom

410, 710

Auger put in to understand linear negative anomaly running from 400,700 to 415 to 715. Hole was difficult to drill because of the tremendous number of stones present from 35-50 cm. The linear low conductivity anomaly would appear to be due to a rock construction

0-35 loose soil with rock, charcoal, and some bone

35-50 large stones

50-65 loose charcoal with soil

65 bottom

Macrobotanical remains

Steve L. Martin

During the 2001 and 2002 field seasons of the Skagafjörður Archaeological Settlement Survey (SASS), a number of sediment samples were collected for macrobotanical analysis. Samples were also taken from excavations being conducted at Hólar by (Hólaskóli, Byggðasafn Skagfirðinga og Þjóðminjasafn Íslands) under the direction of Ragnheiður Traustadóttir. The main goal of SASS (under the direction of John Steinberg) is to chart the long-term (900 years), household level economic change of a number of farms in the northern Icelandic fjord valley of Skagafjörður. The Norse Vikings practiced an agrarian economy in which plants provided fuel, food, building materials as well as summer graze and winter fodder for livestock. Thus, macrobotanical remains those carbonized, desiccated, or waterlogged plant parts that can be identified under low-power magnification recovered from archaeological contexts should offer vital information concerning the economic status of the farms in question. The archaeobotanical remains recovered from various structures at Hólar should likewise yield valuable economic data. Unfortunately, very few macrobotanical studies have been conducted in Iceland (cf. Zutter 1989, 1992, 1997, 1999, 2000). This is most likely due to a perception by Icelandic archaeologists that the intense freeze/thaw conditions prevent macroremains from

preserving in archaeological deposits.

In order to determine if macroremains are in fact preserved in archaeological deposits in the valley of Skagafjörður, a macrobotanical analysis was carried out during the SASS 2001 field season. This report addresses issues concerning the sampling, extraction, and processing of sediment samples recovered during this first season and presents suggestions and recommendations for future research of a similar nature. Samples collected from the 2002 field season have yet to be processed, although they have all been extracted in the field using the mechanical flotation device described below. Subsequent reports will discuss the qualitative and quantitative results of the analysis.

Sampling

After turf structures had been located using remote sensing techniques, trenches were dug so as to allow characterization and dating (via tephra layers) of the structures. Column samples as well as point samples were taken from these exposed profiles (see Table 1). All deposit types exposed in the profiles were sampled (e.g., midden, turf, ash and charcoal lenses). Additionally, a riverbank cut at Reynisstaður exposed a midden deposit that was capped by tephra layers. A point sample was taken from

this profile.

At least two liters of sediment was taken from each location unless the context prevented a sample of that minimum size. This sample size proved to be more than sufficient (see below). The samples were not screened or preprocessed in any way prior to flotation. Column samples were taken from stratigraphic levels that correlated with those of the excavations or, if no stratigraphy was visible, arbitrary 20 cm intervals. Point samples were taken from discrete deposits. Both column and point sample locations were noted on profile drawings. Profiles were cleaned from the top down and sampled from the bottom up so as to prevent contamination. A cleaned trowel was used to collect samples and care was taken to prevent cross contamination between contexts. Samples were tagged with detailed provenience information and bagged in heavy duty (4 mil) plastic zip lock bags of appropriate size. During the 2002 field season of SASS project, 7 sites, comprising a total sediment volume of 232.4 liters, were sampled. Twelve samples, comprising a total sediment volume of 132.1 liters, were recovered from areal excavations at Hólar

Extraction

Flotation is the most common process whereby macrobotanical remains are concentrated and recovered from archaeological sediments. Although there is variation in the construction and operation of flotation systems, they are all based on the same principle: when

archaeological sediments are placed in water, the dense sediment sinks and buoyant plant remains float and are recovered.

Due to the remoteness of the survey area, the lack of necessary supplies, and the inaccessibility of running water, a manual system was employed during the 2001 field season of the SASS project. Sediment samples collected in the field were brought back to the field laboratory and manually floated using the decanting procedure (Pearsall 1989). After the volume of a sediment sample was measured, it was poured into a 10 gallon bucket containing water. The sample was agitated so as to allow plant material to float to the surface where it is then decanted into chiffon netting (0.02 mm mesh). This portion forms the light fraction, which is hung to dry for at least 24 hours. Sediment remaining in the bucket was poured into a 1.0 mm mesh sieve. This yields a heavy fraction, which is dried on paper and saved for future analysis. All heavy fractions were examined for the presence of carbonized plant material.

During the 2002 field season of the SASS and project, soil samples were processed in a mechanical flotation device following Watson's (1976) design and processing procedure. The flotation device consists of a 35 gallon water-filled drum with an insert screen possessing 1.0 mm openings. Soil samples of known volume were slowly poured into the partially submerged insert screen. Low density carbonized botanical remains (light

fraction) float to the surface and are directed out of the drum, via a sluiceway, into chiffon netting (0.02 mm openings). High density carbonized botanical remains are brought to the surface by the action of water agitation and stirring. This procedure is performed until no carbonized plant material is seen flowing into the netting. A siphon is then used to remove any carbonized material that has become waterlogged and remains submerged (Gumerman and Umemoto 1987). Once the siphon process is completed the netting is hung to dry and the material remaining in the insert screen (heavy fraction) is set out to dry and saved for future analysis. All heavy fractions were examined for the presence of botanical material.

Sorting

All dried light fractions were sifted through a series of nested sieves (2.00, 1.00, and 0.50 mm), yielding four size fractions (>2.00 mm, 2.00-1.00 mm, 1.00-0.50 mm, and <0.50 mm) in preparation for sorting. The light fraction is divided as such for two reasons. First, it is easier to sort material of similar size, given the shallow depth of field of the incident light binocular microscope (10-40x) employed. Second, it allows the analyst to selectively remove distinct materials from each fraction. In this analysis, carbonized and uncarbonized wood, carbonized peat aggregates, uncarbonized masses of stems and leaves, and carbonized amorphous material are only removed from the >2.00 mm fraction and weighed. Seeds and seed fragments are removed from all size fractions. The <0.50 mm

fraction is considered residue and is quickly scanned for whole seeds. A representative sample of uncarbonized insect parts is removed from the samples as well. *Selaginella selaginoides* (lesser clubmoss) megaspores, uncarbonized peat moss, and suspected fungal sclerotia are noted but not removed.

In temperate environments, plant material generally decomposes in a relatively short period of time after deposition. Therefore, uncarbonized plant remains usually represent contamination by modern vegetation (Keepax 1977; Lopinot and Brussell 1982; Minnis 1978, 1981). However, a number of deeply buried deposits (>2 m), capped by tephra layers, yielded considerable amounts of uncarbonized seeds. Given the lack of burrowing rodents in Iceland, it is unlikely that these seeds have been introduced into these deposits. Zutter (1999) considered only charred and degraded plant material as being old while items that appeared fresh as being modern. She found that midden deposits preserved uncarbonized plant material whereas the superficial strata of other contexts contained contamination from modern vegetation (Zutter, pers. comm.). I suspect that a high concentration of peat in some of the deposits has produced aseptic conditions allowing the preservation of uncarbonized plant remains. Some of the uncarbonized seeds recovered are clearly modern contaminants, such as the recent alien *Chenopodium album* L. (lamb's quarters) that was recovered from a point sample taken from the upper levels of a trench at Hólar (Sample 17). Since many of the recovered seeds, such as *Stellaria media* (L.)

Vill. (common chickweed) are weedy annuals, their cultural significance must be interpreted carefully. It is clear that the consideration of uncarbonized plant remains will have to be evaluated on a sample by sample basis.

Only the samples from the 2001 field season of the SASS project have been sorted. Thus, qualitative and quantitative comments are of a preliminary nature. The botanical nomenclature used here follows Kristinsson (1987). In addition to the other taxa mentioned, both carbonized and uncarbonized seeds of numerous species of Carex (sedge) have been recovered. The presence of a perigynium on a number of the uncarbonized specimens many allow identification to the species level. Other seeds thus far identified, in carbonized or uncarbonized form, include: *Empetrum nigrum* L. (crowberry), *Hippuris vulgaris* L. (mare's-tail), *Polygonum* spp. (knotgrass), *Ranunculus* sp. (buttercup), *Rumex* sp. (sorrel), *Scirpus* spp. (bulrush), *Vaccinium* sp. (cranberry, bilberry), and *Viola* sp. (violet). Two carbonized and one uncarbonized cereal grains were recovered from Hólar, all of which compare favorable with *Hordeum vulgare* (barley) although the carbonized specimens are highly distorted. Poaceae (grass) seeds of at least four species have also been recovered. A cursory examination of the uncarbonized wood shows most of it to be *Pinus* sp. (pine) whereas all the carbonized wood recovered thus far appears to be *Betula* sp. (birch). Uncarbonized wood and bark of birch has also been recovered. Carbonized fragments of dung and peat have also been recovered.

The large size of many of the light fractions has resulted in the need to conduct tallies (counting but not pulling of seeds). Some samples have yielded seed densities near 500 seeds/liter. Most of these seeds are uncarbonized, but from deep, undisturbed midden deposits. In the future, sub-sampling of the light fractions may be necessary, even for samples less than 2 liters in size.

Recommendations

Sampling. Since the inclusion and interpretation of uncarbonized macrobotanical remains is by no means straight forward, farmhouses abandoned during historic times and present-day farmyard sites need to be sampled. A present-day farm that uses traditional methods of haying and foddering their animals should have its barn floor, fresh hay, feeding trough, and barn refuse deposits sampled. Similar structures and deposits, and turf walls themselves, for a farm that was abandoned during historic times should also be samples. These farm samples, along with modern control samples, will allow structure types to be associated with specific plant assemblages and indicate which taxa are likely to be modern contamination.

Midden samples have yielded the highest diversity and greatest density of seeds and wood (both uncarbonized and carbonized) of all contexts thus far examined. Surprisingly, samples designated as turf wall in the field have yielded very few botanical remains. Again, an examination of the walls of historic turf structures should indicate their botanical

components. Samples of dried, compressed peat should also be collected and subjected to different heating regimes so as to determine its morphology when carbonized or burned to ash.

Extraction. The lack of running water during the 2001 season made the flotation of the sediment samples very difficult and time consuming. A relatively large amount of material became waterlogged and had to be removed from the wet screened heavy fraction. The construction of a mechanical flotation device for the Hólarannsóknin, (Þjóðminjasafn Íslands, Hólaskóli og Byggðasafn Skagfirðinga during the 2002 field season resulted in a much higher rate of recovery and allowed for the use of a siphon to remove any botanical material that had become waterlogged (Gumerman and Umemoto 1987). The mechanical flotation device also proved to be an efficient means

of recovering insect remains found in the sediments samples. Being less destructive than the wet sieving approach typically used to recover such remains, all light fractions from Hólar were examined wet by the archaeoentomologist Magnus Hellqvist prior to drying.

Sorting. At this time, only the samples from the 2001 season have been sorted. All of the light fractions are being examined in their entirety and no sub-sampling has been carried out. As mentioned above, a number of the samples contain a rather large amount of uncarbonized plant material, most of which is modern contamination. In the future, adjustments to the sampling procedure (i.e., vary sample volumes by context) should make the examination of light fractions more manageable.

Insect fossils from Hólar

Magnus Hellqvist

During the 2002 excavations at Hólar in Hjaltadalur, several samples were sampled for different analysis. There was a unique occasion to follow the progress at the excavation and to simultaneously process soil samples, and also bone samples, as they were collected. This provides not only good possibilities to direct dialogue with archaeologists in field and the interpretation of the constructions or layers, but also makes the planning for the next years excavation easier.

The simultaneous work also creates an understanding for the archaeological fieldwork and different analysis methods in connection to the archaeological work. There are possibilities for direct dialogue and discussion during work with the field context.

The work with the insect fossil samples the first year, raised questions and aims for the continuation. There is a 18th – 19th century floor sample in context 89 in the remnants of the printing house. The insect fossils from this context were well preserved and provides an interesting historic floor sample to be compared with the floor samples from other houses in Hólar. This may when compared with other samples provide interesting insight to the beetle composition in houses at Hólar, in the same local environment. This also makes it very

interesting to sample modern and submodern samples in the surroundings of Hólar, together with stratified peat of some age to get a picture of the environmental conditions of the valley and how this affects the beetle fauna.

The fact that samples are taken during the excavation and are processed simultaneously, with possibilities of insight in the stratigraphical record, starts a dialogue between archaeologists at field and those working with different methods, mainly in laboratory. This opens for good opportunities of method development.

There are particular questions connected to the interpretation of beetles fossils. Any possibilities to interpret the local or regional climate is of big interest, especially in the light of human settlements and changes within that. This may though be difficult since the human settlement presents special conditions that may rule out the dependency of climate and usually are beetles attracted that are more attracted by substrates and human habitats. The human environment interpreted from insect fossils is always of interest, the opportunity of samples representing different time units in the same environment, like indoors, makes this results even more interesting from several angles. There is similarly interesting to use any method to increase the understanding of the

use of the house and its different parts through time. An interesting question is whether there it is possible to see any site status from the palaeoecological record, in the same way as was presented in Amorosi et al. (1992) in investigations at Bessastaðir. Especially since Hólar also represents a site with known status.

Sampled areas at Hólar and method

The excavated area in Hólar was divided into several smaller or bigger excavation areas (A-F). Briefly they can be presented as follows, but the archaeological information (personal and described) is best for more precise description and interpretation.

- A smaller trench, disturbed, but with remnants of a fire place with slag after iron work. Interpreted as old. **No samples for insects fossils.**
- A larger shaft, with a toplayer where there was found remnants after a building from 1905. A larger trench was opened and under the “modern” building there was a partly turfwall in the south; followed by a black bad smelling organic layer in the centre - **sampled for insects fossils;** finished in the south peat ash layer with charcoal - **sampled for insects fossils.**
- A smaller trench. **No samples for insects fossils.**
- The largest shaft with the remnants of the former printing house. During a period after the printing activity, the house was used to stable horses during the 19th century. **Samples for insects fossils** was collected

in on part with lots of twigs and organic material, interpreted as a fallen roof, overlaying a interpreted layer of dung.

- A larger trench that was laying in more or less north-south direction, with a stratigraphy of layers (101-112) described 2001 in a smaller test trench and 2002 investigated more expanded in the bigger trench. In the upper part the layers was interpreted as from a midden, of very present age. Further down there was remnants of a what is interpreted as a house (layer 104) – probably of old age. The overlaying turf layer (105), is most probably a layer from the house during decay. **Samples for insects fossils** was collected in all layers until layer 104, where the excavation stopped at 2002.
- A smaller trench, where a tunnel was found. **No samples for insects.**

Samples for insect analysis was washed through a 0.25 mm sieve. Macroscopic remains of insects were sorted out from the sieve residue under a stereomicroscope at low magnification. The identification of the remains is usually carried out using keys for modern specimens and by comparison with modern specimens from reference collections.

Subfossil beetles (Coleoptera) dominate the record and is the main group to be studied. All the species found are present in the area today. Remains of puparia of true flies (Diptera) were also found, but are not further discussed in this paper. But, the Diptera finds will be studied in separate investigation by Dr Eva

Panagiotakopulu at University of Sheffield,
Department of Archaeology and Prehistory.

Studies of macroscopic plant remains is also performed in Hólar project. Dr Steve Martin has collected samples and sub samples for studies of macroscopic plant remains in the same sample as collected for insect fossil remains studies. This increase the strength of the environment investigation at Hólar. Also pollen analysis is supposed to be established around the settlement.

Preservation in the samples and diversity

The preservation degree in the samples is generally very good. There were few fossil remains with oxidised or very bleached surface, colour was normally good but sometimes pale. The majority of the remains are easily identifiable.

During the work with the samples some questions were raised about the diversity of the beetle composition of the samples. Even when a relatively high number of remains of beetle fossil parts was found. The diversity could be ruled by factors like for example bad preservation, the deposition history of either the excavated and sampled feature or the behaviour of the beetles.

Usually bad preservation makes small species disappear quicker than larger specimens, but bad preservation conditions is usually easy to recognise also on remains of the larger specimens. Deposition history (taphonomy)

is together with the beetles behaviour the most important factors affecting the beetle composition diversity. In a settlement area there are several habitats and substrates that may attract insects and several insects have adapted to these environment, so there may be a large number of species and individuals in these deposits. Middens and storing areas are such deposits. Species may also be trapped during flight or/and search for food, like in wells. There is also the opportunity that species of insects may accidentally be transported to a deposition in an environment where they normally do not live, like in building materials for houses.

Finally there are species that find more suitable living conditions in the human environment than in the natural environment, sometimes they may as a consequence of this live further north than normally. Habitats in this group are as example attractive substrates – like dung, stored food, large areas of cultivated plants etc, warmed houses or other human created habitats. This group of insects is of course very interesting in work with human settlements. The group is referred to as *Synanthropic*.

The composition of the beetle species in samples from Hólar investigations 2002, are similar to compositions found in other excavated areas where the samples are mainly collected from inside houses – like old floor layers or remnants of a decayed house, mainly roof remnants. The other excavated settlements are Bessastaðir á Álftanesi (samples from indoor, collected 1993), Hofstaðir í Garðabæ (collected

between 1994-1996 and 1998), Keldur á Rangávöllum, Eiríkstaðir í Haukadal (collected 1997; Hellqvist, unpublished) and Breiðavik (Hellqvist, 2001).

Soil properties

The soil properties are generally sandy silt, clayey silt and silty clay. The clayey silt is usually the most common variant. No loss on ignition has been tested to the soil samples this year, but the organic content is probably generally quite high. This may be concluded, since the samples are rich in organic particles like seed, wood fragments, twigs, insects etc

Results and discussion

The complete insect analysis is still to be progressed, but some general results and a few beetle species may be discussed. The most common species found in all samples, which is also relatively rich in number of individuals, is the weevils *Otiorhynchus nodosus* and/or *Otiorhynchus arcticus* – the two species are very similar and are best separated in reference collection. Sporadically in samples from house floors the beetle *Lathridius minutus* occur. Another species common in floor samples or from inside houses is the spider beetle *Ptinus fur*. Information on the biology of the species is from Larsson and Gigja (1958) and Palm (1996).

The weevil species *Otiorrhynchus nodosus* and *O. arcticus* are both living in quite common habitats. They are usually found in Iceland at drier habitats. *O. arcticus* may also be found

in dryer and meagre habitats, it is also found on sandy ground with little vegetation and heaths, but on the contrary it may also be found along river banks both rich and poor in vegetation. *O. nodosus* is found in many varied biotopes (eurytopic) in moss and under stones. The beetle and its larvae's feed on a variety of plants (herbs). They are *not* particularly bounded to human environments or living in close association with man (synanthropic) and therefore it was probably introduced into the sampled houses either during the building time of longhouse and/or pit house, most likely in the building material, or it came in to the house by accidental transport in substrates – for example in fodder if the building was used as stable.

Lathridius minutus is common everywhere in Iceland and it is only *synanthropic* and is feeding on mould, spores as well as hyphae. The spider beetle *Ptinus fur* is also *synanthropic* and found inside houses. It usually originate in birds nests, but spider beetles larvae may infest all manner of dry animal and vegetable matter including grain, spices, fish meal, dried fruit and a wide variety of miscellaneous debris. The adult *Ptinus fur* may also damage packaging bags and sacks. The species is today usually on listings of *common pests* indoors, but the interpretation can not automatically be in this direction until there are more (more individuals of this species and other species) and other indicators (in plant remains etc) in this direction.

Conclusion 2002 and questions 2003

1. Preservation degree is generally satisfying, which points in the direction that there are good opportunities to collect samples for palaeoecological analyses like insects and plant remains. The results of pollen analysis is still to be explored.
2. Samples from natural deposits in the surroundings would improve the interpretation of the samples from cultural deposits.
3. In area D, context 82, the beetle remains verify the both written source and excavated part of the building, interpreted as stable. There is also found parts of what is interpreted as dung.
4. In area E, context 109 and 108, the layers are mixed and modern. The beetle remains are species connected to the plants living on the spot or connected to similar deposited as trash.
5. In area E, context 107 and 106, the beetle remains may well be species deposited as trash with plant remains but probably of sub recent or historic age.
6. In area E, context 105, the beetle remains - due to low diversity and indications of indoors - points to the conclusion that the layer has its origin from a building. The layer may be decayed part of a building, being remains of wall and/or roof.
7. In area E, context 104, the beetle remains similarly to context 105, points to the conclusion that the layer has its origin from a building. Also the archaeological interpretation is that this layer is from a building.
8. Changing development in Hólar during 900 years, both indoor and in the settlement environment.
9. As the excavation continues, questions always rise about how the houses have been used and insect remains is one way to interpret the use of parts or the whole house.
10. The closely related and simultaneously work between field archaeology and analyses, creates good opportunities for method development.
11. An important aim when working with beetle remains, if possible, is to interpret local and regional climate.
12. The relations between human settlement and the natural environment is always important and the close relation between man and nature in Iceland increase possibilities to understand this..
13. A common question for interpretation of both insect remains and bone remnants, is to explore to recognise any site status through the palaeoecological record as Amorosi et al. (1992) has presented from Bessastaðir.

Preliminär Osteologisk Analys – Djurbensmaterial

Ylva Bäckström

Den osteologiska analysen omfattar benmaterial från årets (2002) arkeologiska undersökning av biskopssätet Hólar i Hjaltadal på norra Island. Undersökningen ingår i ett flerårigt forskningsprojekt (*Hólarannsóknin*) under ledning av Ragnheiður Traustadóttir. Projektet är tvärvetenskapligt och omfattar ämnena arkeologi, ortnamnsforskning, historia och naturgeografi. Projektets mål är bl a att undersöka biskoparnas/biskopsätets ekonomi, bebyggelsestrukturer och hustyper, samt granska förbindelser mellan Hólar och andra nyckelorter i området bl a landnamsgården Hof, hamn- och handelsplatsen Kolkuós samt klostren på Þingeyri och Reynistað. I detta avseende kommer ytterligare arkeologiska undersökningar, av bl a Hof och hamnen och handelsplatsen Kolkuós, att genomföras.

Målsättning

Den övergripande målsättningen är: att allt benmaterial som kronologiskt kan bedömas ska analyseras. Av största vikt är att man vid fältarbetet samlar ben från olika kontexter/lager i separata påsar så att inte kulturlager från olika tidsepoker sammanblandas.

Analysen av benmaterialet kommer att inriktas på:

- de undersökta platsernas ekonomi (Hólar, Hof och Kolkuós) och om möjligt även deras sociala status.

Benmaterial från boplatser kan, tillsammans med övrigt fyndmaterial och kontexter, ge indikationer på hög status kontra låg status. Andelen jaktvilt är t ex i Sverige generellt sett liten på järnåldersboplatser. Men förekomst av jaktvilt samt en hög andel slaktade ungdjur bland tamboskapen skulle kunna indikera en ”rik” boplats (se t ex Vretemark 1989). Även fynd av rovfågel, framför allt i gravar, tolkas som statusmarkörer. Men skillnaderna i artrikedom mellan det fastlandsskandinaviska området och Island gör att man ställer sig frågan om samma statusmarkörer har existerat? För att kunna se skillnader i status krävs ett referensmaterial, d v s i detta fall sammanställningar av hittills analyserade benmaterial på Island, för att tydliggöra skillnaderna mellan en ”normal” gård och en gård med ”högre status”. I detta sammanhang är det även intressant att undersöka handeln i Kolkuós och handelsförbindelser med de övriga platserna som kommer att undersökas. Framför allt kan förekomst av arter som inte finns naturligt på Island påvisa långväga handel, något som troligen enbart kom människor med större rikedomar till godo.

Intressant är även att undersöka skillnader i ekonomi mellan förkristna och kristna

kontexter, framför allt mellan Hof och Hólar.

- den rumsliga indelningen av olika enheter (hus, gård och by) (matförråd, slaktområden, hantverksområden m m). För att kunna tolka analysresultatet bör detta illustreras genom spridningskartor med olika parametrar (t ex slaktavfall, matavfall, bearbetade ben, brända ben o s v). Resultatet av benspridningen kan även kombineras med fyndspridning, undersökta anläggningar, ev fosfatkartering och ev en analys av organiskt material och spårämnesanalys av jord och keramik.

Det analyserade benmaterialet från samtliga undersökningar ska sedan sammanställas och genom jämförelser med tidigare undersökta material infogas i ett vidare, geografiskt och kronologiskt, perspektiv. Av intresse är framför allt jämförelser med samtida högstatusmiljöer i Skandinavien. Vilka djur har ansetts förhöja en rituell/religiös eller världslig ledares status och anseende? Förekommer det skillnader mellan de nordiska länderna?

Preliminär Osteologisk Analys

Stora mängder obrända djurben samlades in från säsongens undersökningar i Hólar och sammanlagt har nästan 60 kg ben analyserats. Ytterligare ben samlades in, men ansågs härröra från omrörda och störda lager, och har därför uteslutits ur analysen. Analysen är preliminär, eftersom en stratigrafisk analys av de undersökta ytorna ännu inte har gjorts. En mer utförlig rapport med metodbeskrivning

planeras till nästa säsong (2003).

Materialet består nästan enbart av obrända djurben och är mycket välbevarat. I genomsnitt väger ett benfragment omkring 10 gram.

I analysen ingår en art- och benslagsbestämning (inklusive bestämning av bendel och sida), en köns- och åldersbedömning om möjligt, samt en kvantifiering (antal fragment, vikt och beräkning av minsta individantal (MIND)) av materialet (Silver 1969). De ben som inte har kunnat bestämmas till art eller benslag har enbart vägts. Dessutom har sjukliga förändringar eller andra förändringar på benen noterats (t ex spår av slakt). Som underlag till mankhöjdsberäkningar har mätningar av framför allt mellanhand- och mellanfotsben gjorts (Driesch 1976, Howard 1963, Koudelka 1885, Teichert 1975). Ben från får och getter kan vara svåra att skilja från varandra, men vissa skillnader finns på både tänder och andra ben (Boessneck 1969, Payne 1985). Samtliga data har registrerats i en databas. Som referensmaterial har bensamlingen från den osteologiska avdelningen på Statens Historiska museum i Stockholm använts.

En indelning av benmaterialet i primärt slakt- och matavfall har gjorts för område D, lager 89.

Om andelen köttrika ben (matavfall) överstiger 38,5 % av det totala antalet benfragment så betyder det att matavfallet är överrepresenterat. Detta är ett medelvärde som beräknats utifrån en procentuell uppskattning över hur stor andel av skeletten av får/getter (41 %), kor (41 %) och grisar (36 %) som består av köttrika ben (Sigvallius 1988 s 43f).

Resultat

Det analyserade materialet innehåller ben från de vanliga tamdjursarterna får, nöt, häst, hund och gris, fig 1 och 3. Ben av får dominarar stark, men även en hel del ben av ko förekommer. Endast ett fåtal fragment av häst, hund och gris är funna. Förekomsten av vilda däggdjursarter är liten, vilket speglar faunan på Island. De vilda däggdjursarterna representeras av ben från säl, antingen grå- eller knubbsäl, och val. De valben som har hittats är bearbetade och är omöjliga att artbestämma. I materialet finns även stora mängder av fisk och fågel, framför allt ben av kolja och sillgrissla, fig 2. Andra fågelarter är korp och andfågel.

Spår av slakt kan iakttas på flertalet ben av

får, ko och häst. Man har även tagit vara på märgen, varvid två olika tekniker har använts. Antingen har benen, framför allt mellanhand- och mellanfotsben av får, märgkluvits vertikalt, eller så har hål borrats både i den proximala leden och på benskaftet ovanför den distala leden. Det sistnämnda har jag aldrig påträffat tidigare i något material. Ett test på hur fördelningen av slakt- och matavfall i område D visar en övervikt på matavfall, fig 4.

I benmaterialet från undersökningen av en medeltida gård i Herjólfssdalur på den nordöstra delen av Heimaey förekommer i stort sett samma djurarter som i Hólar, men ben från hund saknas, andelen tamsvin är betydligt högre och mängden fiskben är mycket liten. Bland fåglarna finns arter som havssula, tamhöns, sillgrissla och framför allt lunnefågel, vilken hittills inte har kunnat konstateras i materialet från Hólar (Hermanns-Auðardóttir 1989 s 122ff). Man bör ha i åtanke att detta material sannolikt inte är samtidig med de lager som hittills har undersökts i Hólar. Vid undersökningen av de senmedeltida lämningarna i Bessastaðir hittades fynd av får, nöt, häst, gris, torsk och räv. Benmaterialet från tidig modern tid (1600-1849) uppvisar en större artrikedom, där även tecken på handel kan skönjas genom t ex förekomsten av brunråtta. I materialet finns även ben från valross, isbjörn och lax, vilka tolkas som viktiga handelsvaror. Fyndet av räv kan även indikera att handel med päls förekommit (Amorosi m fl 1992 s 172ff).

Soil coring

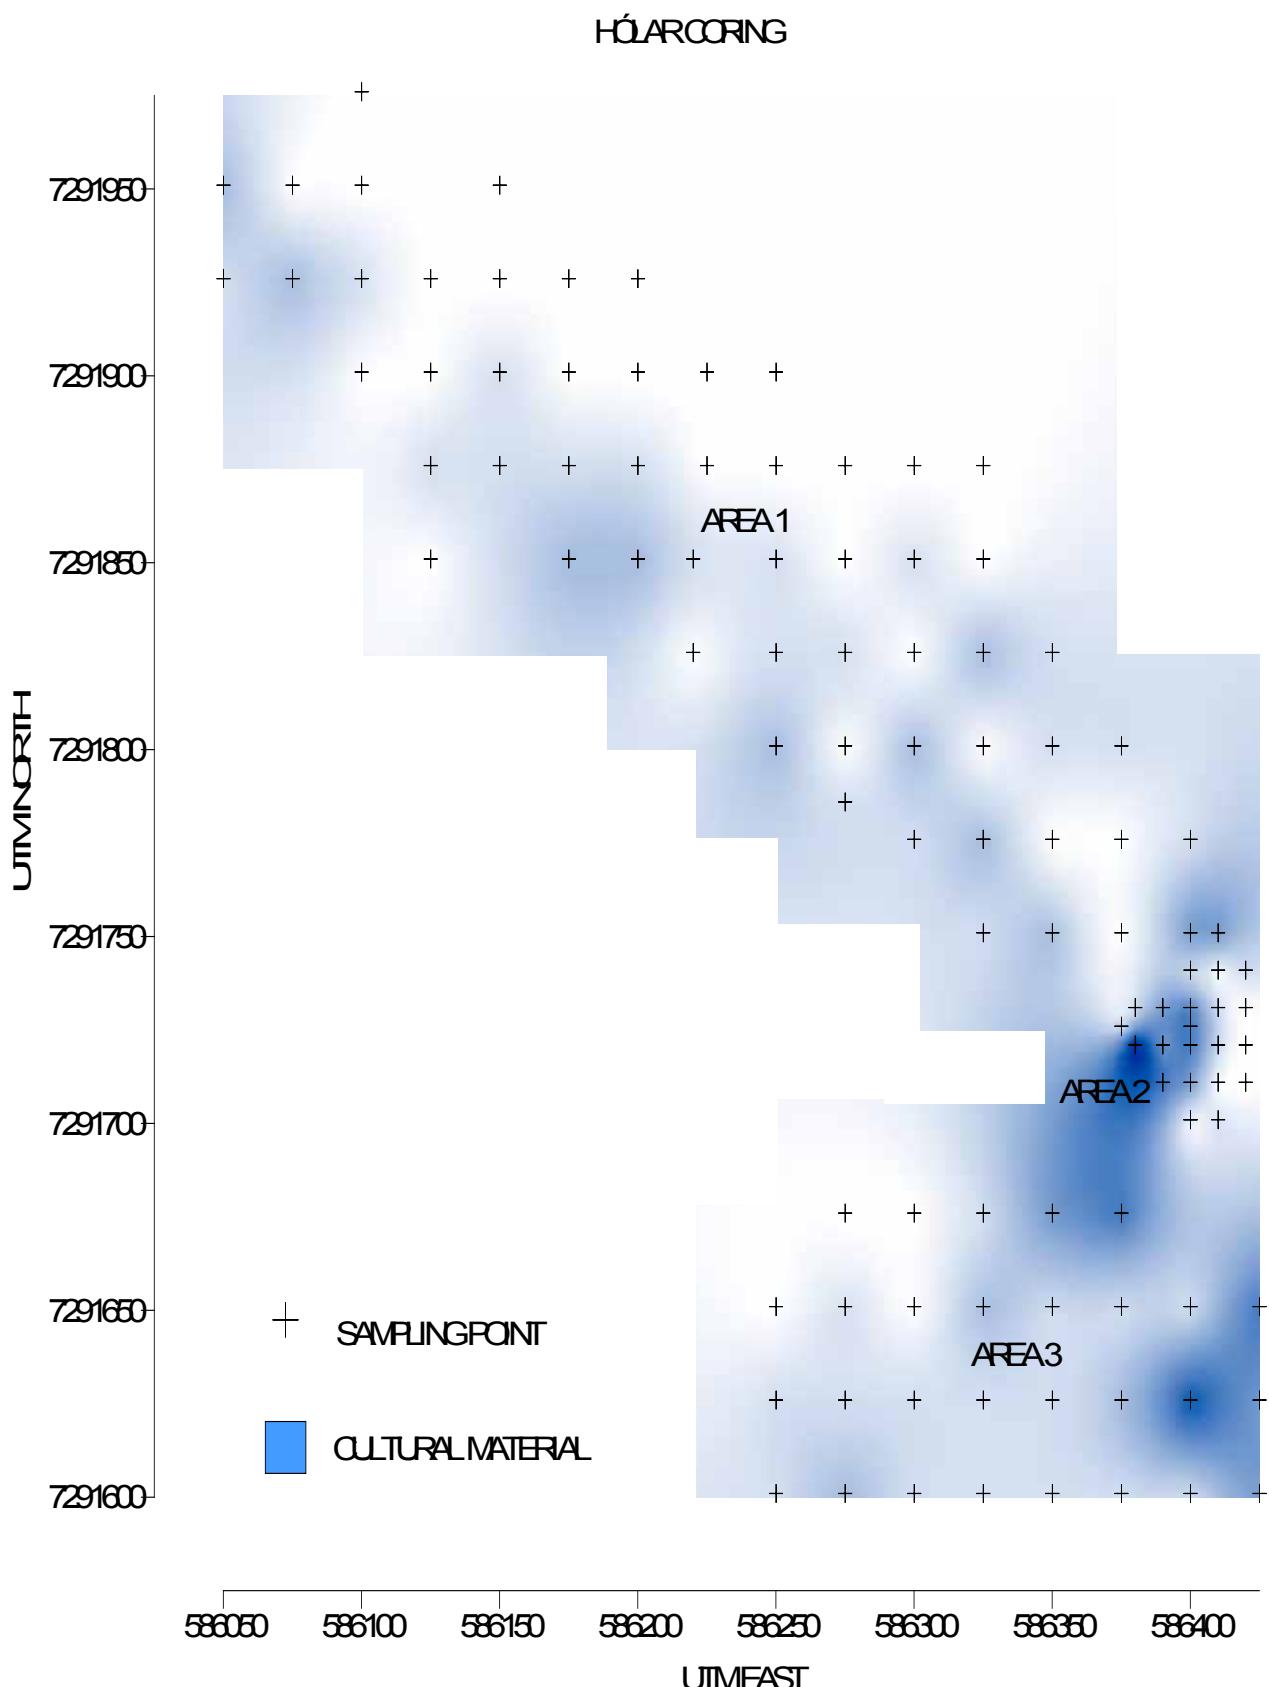

Douglas Bolender

The fields to the southwest and northwest of the church were sampled.

The field northwest of the church (AREA 1) has the least intensive activity of the areas sampled at Hólar based on the presence of cultural material in core profiles. Cultural material is group in three main areas, each associated with evidence, such as turf debris, for past structures. In the area furthest away from the church structural remains are still visible on the surface. The concentration of cultural material around structural remains probably represent areas of agricultural intensification around out-buildings. Cultural material was identified in all soil horizons dating from after the Hekla 1104 tephra. However, tephra was not preserved consistently enough to date the relative intensity of activity areas and land-use based on the coring profiles alone.

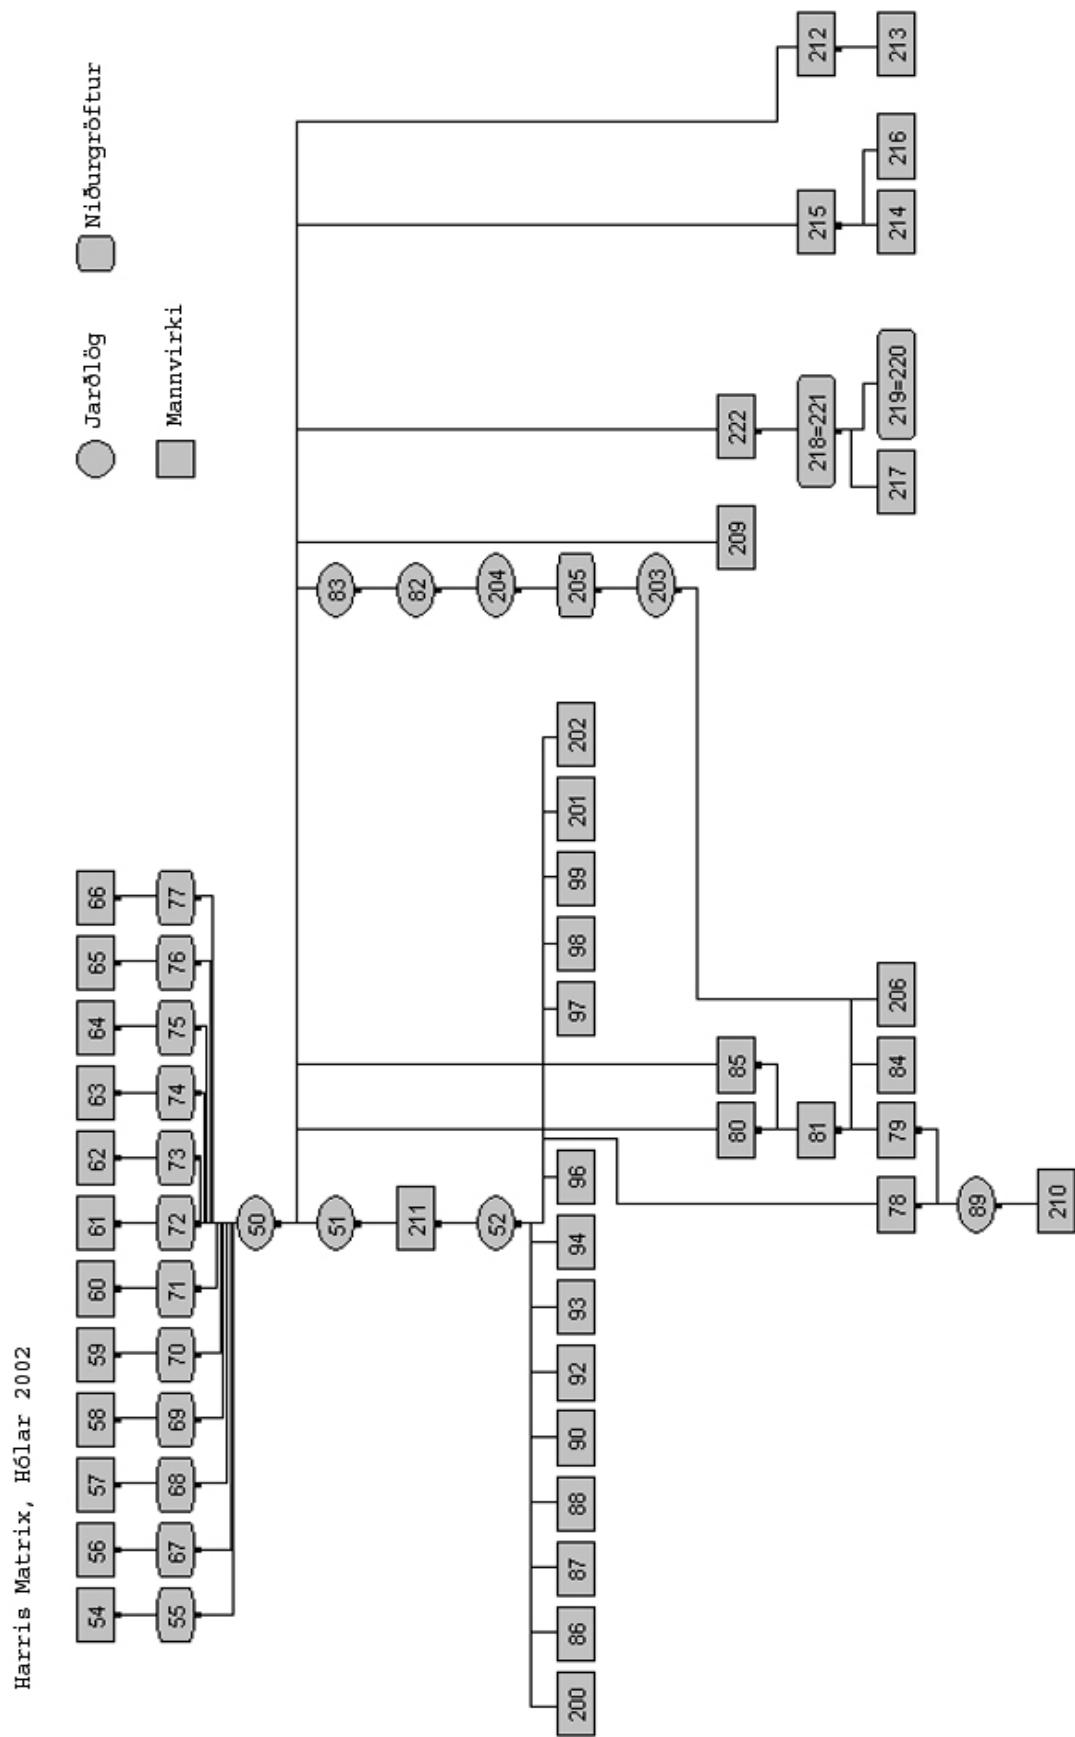

The areas immediately northwest and southwest of the church (AREAS 2 & 3) show intensive land-use in the past. Coring profiles revealed large amounts of scattered cultural material – bone, charcoal, and peat ash – throughout the soil horizons and widespread midden deposits in these areas. Cultural material was identified in over 80% of the core profiles, many with multiple layers of mixed cultural material and midden. Due to the concentration of cultural

material and the obvious intensive land-use of this area in the past, it is difficult to distinguish areas of agricultural enrichment from other areas of human activity resulting in geo-chemical enrichment of soils. Distinguishing the areas and sequence of past land-use at the site will require extensive excavation and detailed coring to identify and distinguish buildings, cultural layers, and midden deposits from agricultural lands.

Jarðlagaskrá

Id	Area	Context	Length(m)	Width(m)	Description	Method	Relate to structure
50	Area D	Disturbed layer	34.37	29.57	Topsoil [50] is a deposited and disturbed cultural layer. Grayish brown sand-mixed humus. Part of the midden that lay in the area. Contains finds that span from the middle of the 17th century to modern times and a large number of animal bones. The layer covers the initial trench and the whole extent of area D.	Trowel Sieving Shovel	
51	Area D	Midden layer	13.94	7.93	Midden [51]. Brown mixed soillayer, lots of unburned bones.		
52	Area D	Cultural layer	10.37	3.98	Cultural layer [52] Brownish red with plenty of charcoal, ash and peatash.		
53	Area D	Turf collapse	20.95	8.5	Mixed turf layer [53] with comprised of several different colours.		
55	Area C	Disturbed layer	0	0			
82	Area D	Roof tumble	2.31	1.85	Roof tumble [82] is a disturbed turf layer inside turf wall [81]. A lot of twigs and bark fragment. Few finds. Interpreted as a collapsed roof.	Trowel	8
83	Area D	Cultural layer	39.7	32.3	Greyish brown turf layer mixed with earth. Disturbed fill layer. Contains plenty of windowglass, ceramics, and clay pipes.	Trowel Sieving	8
89	Area D	Cultural layer	13.63	8.57	Brown light soil [89] with inclusions of clay, lots of unburned bones.		
107	Area E	Midden layer	7.3	6.2	Midden layer [107] is moderately compacted brown with yellowish inclusions consisting of mixed turf with frequent inclusions of bone fragments and occasional charcoal. Extent not applicable because of limit of trench. Interpreted as fill of midden.	Trowel	3
108	Area E	Midden layer	4.02	2.11	Midden layer [108] is the same as 10 000 from 2004. It is a mid reddish brown silty sandy deposit of moderate compaction. It is rich in charcoal and bone and sub-angular small stones, medium in degree of sorting the extent is not yet applicable because of limit of trench. Interpreted as fill of midden. Modern origins; Pick axe retrieved!	Trowel	3
109	Area E	Midden layer	7.84	6.26	Midden layer [109] same as [10002] in 2004. It is a fairly loose silty sand deposit dark blackis brown in colouring. Frequent inclusions of charcoal flecks and bone fragments and moderate amounts of small angular and subangular stones - Occasional medium sub-angular stones (both poorly sorted). Extent not applicable because of limit of trench. Interpreted as fill of midden. Modern deposit. Topsoil; result of modern disturbance, reversed stratigraphically.	Trowel	3
110	Area E	Midden layer	2.04	1.3	Midden layer [110] same as[10001] from 2004. Moderately compacted, dark orangey brown silty sand. It has occasional inclusions of charcoal. Moderate amounts of small angular and sub-angular stones medium in degree of sorting. Extent not yet applicable because of limit of trench. Depth. 0.11m as in section drawing #2. Interpreted as fill of midden. Modern origins.	Trowel	3
151	Area A	Cultural layer	2.95	2.21			
202	Area D	Cut	0.1	0.08			
203	Area D	Floor	2.3	1.63	Turf floor [203], inclusions of hair from animals, hay. Few finds. Interpreted as floor inside a stable (byre).	Trowel Sieving	8
208	Area D	Turf wall	10.61	4.03	Turf wall [208] is built out of orangish brown turf with white inclusions which appears to be white sand from thermal areas. Also contains a bit of clay that turn white and cement-like in dry and sunny conditions. Similar turf that has been used in the wall [63642] south of the printhouse. The wall [208] is the western boundary of house and [9] in the east confined by wall [218] and [81]. It is roughly L-shaped, 11x4m, oriented NNW-SSE, with one arm extending towards East, separating house [6] and [9]. The wall is 1,2-0,9m Wide and has been built using klífumpruhnaus (wedged blocks of turf) and strengur. House [9] appears to have been built using more strengur or torfa and even snidda at the Northern most part.		
218	Area D	Turf wall	10.61	7.43	Turf wall [218] bounds House [13]. Exposed since 2003 therefore heavily eroded over time. Eastern side (e.g. towards Church) is all but gone, having fallen into the large hole created by the modern statue that used to stand on the site. Due to erosion and bioturbation (by worms and tree roots, especially in the south-west corner of the House) it is very difficult to define the wall or observe its relationship with other contexts (e.g. layers covering the floor area). The wall appears to merge with a stone 'pavement'/corridor above it and to the North; a row of stones was found under the top layer of turf during cleaning, which might be a lower level of this 'pavement' (perhaps made of turf and stone layers). close to the middle of each beam (which would jolt them together with "side beams") is interesting. The fact that they are found inside a wall structure remain unclear, since it is unlikely that precious wood would be used as invisible fill.		

Id	Area	Context	Length(m)	Width(m)	Description	Method	Relate to structure
301	Area B	Cultural layer	0	0	Surface layer [301] is turf or grass that was taken off of the area in the beginning of excavation.		5
302	Area B	Cultural layer	8.06	8.06	Topsoil layer [302] was under the surface layer [301]. The layer covers the whole area B and is very disturbed, mixed and compact. It lies on top of turf walls in the area and inside the buildings. A lot of finds were found from different time, pottery, iron, modern glass, charcoal, bones and etc.	Shovel Trowel	5
303	Area B	Fill	4.7	0.9	Fill ditch [303] is situated in the SA corner of area B and reaches 5 m to the west, up against the south bank of the excavation. The soil is quite compact and clayey, full of small stones from 2 - 3 cm, the biggest about 20 cm. The layer covered a part of a turfwall in the area and it looks like this layer was dug through a small part of the turfwall. In the south corner of the building there was a little bit more of this layer. There were burned bones in the layer and recent finds.		5
304	Area B	Gravel	0	0	[304] is a very mixed layer. It consists mostly of red gravel from mixed with soil, small pieces of charcoal and small amounts of peat ash. The layer is rather loose and coarse. It extends 1,6 m beyond the limit of the excavation area on the N side and is about 1 m in width. Disturbed layer [302] was on top of [304]		5
305	Area B	Cultural layer	0	0			5
306	Area B	Roof tumble	5	3.2	Roof tumble [306] is a mixed and collapsed turf from the roof of the building. There were some 1766 tephra spots in the turf except in the southeast part. There were some stones and wood and among the finds were some iron objects and pottery. Below [306] was a layer with a lot of iron and charcoals (some of the iron is from early 20th century).		5
307	Area B	Turf collapse	7.85	0	Mixed turf [307] in Area B. This layer is very organic and has no inclusions. It is compact and fine grained.		5
308	Area B	Turf collapse	7.5	2.2	Mixed turflayer [308] is outside of the building. It had turf in many colors that are probably collapsed walls or roof. It contains a few stones, treeplank, iron objects, pottery and ect.	Shovel Trowel Sieving	5
309	Area B	Fill	2	1.5	[309] is a back heap of charcoal, ash and soot with slag and iron objects. It is on top of a sill of wood and turf [319].		5
310	Area B	Floor	4.7	2.15	Floor layer [310] made-up of a thin layer of sandy black charcoal and ash. Lots of finds were associated with the top of the layer including: horseshoes, rods, nails and a bucket. The layer was lying on horizontal squares of turf [320].		5
311	Area B	Disturbed layer	3.1	2.9	[311] is a brown, disturbed, clayey layer mixed with turf, charcoal and red sandstone.	Trowel	5
312	Area B	Cut	0.35	0.25	Cut [312] has a fill of recent white glass.	Trowel Shovel	5
313	Area B	Cut	4.65	0.4	Cut [313] for ditch in the southern part of the trench. The fill of this cut is [303]. The cut had a stonewall of stones that were about 10 cm in diameter.		5
314	Area B	Turf wall	3.69	0.45	Turf wall [314] is the eastern turfwall of the building in Area B.		5
315	Area B	Turf wall	3.96	0.51	Turf wall [315] is the western turfwall of the building in Area B. It consists of colorful turf squares. No stones were found.		5
316	Area B	Turf wall	2.07	0.51	Turf wall [316] is the Northern wall in house 5 in area B. The wall seems to be built up by kramber and the turf has some tephra 1766. The wall has not been excavated just partly exposed.	Trowel	5
317	Area B	Midden layer	2.15	0	Middenlayer [317] is an orange-black peatash layer with charcoal and a rich amount of burned bones, situated beside pit [303].		5
318	Area B	Peat ash	1	0.45	Peatash layer [318] is located below the structure in Area B and had inclusions of charcoal.		5
319	Area B	Wood	1.3	1.25	Wood [319] fundament with turf. The turf has lightyellow organic material in it. The turf itself is brown, wet and quite compact. The construction was below [309] which was a black heap of ashes, charcoal and slag with lots of iron objects. The two wood pieces lie in the same direction, 1 meter apart. Some black material lies under the wood plank further to the south.		5
320	Area B	Floor	0	0	Turf layer [320] is a foundation for the floor in the house. The turf lies horizontally and this is the foundation that floor layer [310] accumulated on.	Trowel Sieving	

Id	Area	Context	Length(m)	Width(m)	Description	Method	Relate to structure
321	Area B	Peat ash	1.12	1	Peatash layer [321] is mixed with clay and situated below turfwall[315] of the structure in area B. One iron object and a bronze object were found in the layer.		254238
323	Area B	Peat ash	0	0	Mixed layer of peat ash, small stones, brown clay and turf. The stones had the dimensions 5-15 cm.		254238
324	Area B	Cultural layer	0	0	Cultural layer [324] is a yellow clay layer. There are some charcoals and small stones around 5-7 cm in the layer.		254238
325	Area B	Cultural layer	0	0	[325] is a burned layer with charcoals that are around 4 - 8 cm.		254238
326	Area B	Turf collapse	0	0	Mixed turf [326]. Yellow brown mixed layer of turf twiggis and wooden pieces. Finds: stone bakingplate, a piece of a soapstone bowl, that might contain some food remains.		254238
327	Area B	Cultural layer	0	0	[327] is a reddish brown sandy soil with lots of stones.		254238
328	Area B	Midden layer	0	0	Midden layer [328] consists mainly of peatash, burned bones and charcoals.		254238
329	Area B	Cultural layer	0	0	[329] is a turf deposit mixed with soil. It smells bad, might be brennisteinn. Soilsample was taken from it. It is the same layer as \b [333].		
330	Area B	Peat ash	0	0	[330] is a peatash deposit mixed with turf.		254238
331	Area B	Cultural layer	0	0	[331] is a greyish brown clay with small amount of charcoal.		254238
332	Area B	Cultural layer	0	0	[332] Tephra layer insitu (H1766?). It is greenish grey in color.		254238
333	Area B	Cultural layer	0	0	[333] is a greyish brown clay deposit and has stones in dimensions of 5 cm. In the western part the layer becomes more black-brown-grey and consists of burned bones and charcoal. The interpretation of the layer is deposit. Four soil samples were taken.		254238
334	Area B	Turf wall	0	0	Turf wall [334] consists of horizontal turf (possible turfwall). The turfwall is thikkier in the east end circa 25 cm but only 10 cm in the west end.		254238
