## RESERVOIR PARAMETERS

### Data on cores sent to Greg Boitnott

The data of the samples sent to Greg Boitnott is described in the following ways:

#### Field characteristics

G-samples are taken in a tertiary extinct deeply eroded central volcano called Geitafell in SE-Iceland, which have suffered high-T alteration. The H-sample is taken from a low-T environment of tertiary age in West-Iceland, and R- samples are taken from an interglacial relatively fresh olivine tholeiite lava-shield within Reykjavík.

G-8 The core is taken from a plagioclase porphyritic, flow-lineated basalt lava flow. The core is taken from the lower more vesicular part of the flow. Vesicles are filled by light-green clay (probably chlorite), zeolites (scolesite, laumontite), and epidote veining is observed in the rock.

G-13 A very epidote-rich re-sedimented basalt hyaloclastite. Size of fragments <1cm.

G-14 A 1-2 m thick strongly flow-lineated rhyolite dyke: the core is taken parallel to flow-lineation. Within chlorite-epidote zone.

G-28 A basalt breccia within Smectite-zeolite alteration zone. Void spaces largely filled with zeolites.

H-78 A relatively dense and coarse-grained olivine tholeiite lava flow from a monogenetic shield volcano in W-Iceland, within the smectite-zeolite zone.

R-34 and R-43 These two samples are taken from an olivine tholeiite lava shield within Reykjavík. Petrographic analysis have not been made at this time, but rocks are assumed to be fresh, except that some opalline material is seen to have precipitated in some of the vugs in the lavas.

#### Petrography

The main characteristics of the rock samples have been assessed in the petrographic microscope by using 200 point counts of specific features in the rock presented in %. These include; % Primary minerals in the rock (plagioclase, pyroxene, olivine, ore, glass), % altered primary minerals, %minerals precipitated in "primary" vesicles in the rock, % "primary" vesicles that have not been filled by deposition, % deposition within fractures and % open fracture space. These values are shown in the accompanying tables.

Petrographic analysis have not been done on the R-samples as mentioned previously. The clay portion in the samples have not specifically been assessed, but one can assume that samples G-8, 13 and 14 have considerable amount of clay content (should be mainly chlorite), in samples H-78 less clay content (mainly smectite), and R-samples would only have minor clay (smectite).

#### Chemical analysis

Chemical analyses are shown in accompanying table. These are "standardized" rock analyses, where the major element oxides are presented as %, while trace elements are presented in ppm. %LOI (Loss Of Ignition), %CO<sub>2</sub>, % FeO were analyzed additionally. Samples R-34 and R-43 were not analyzed specifically, but samples R-39,42,51 & 52, which are from the same volcanic formation are included for comparison.

#### Measurements of reservoir characteristics

The measurements of the reservoir characteristics are shown in the accompanying table, but is not described any further here.
